1 Overview

Features

- Wide Input Voltage Range from 3.0 V to 40 V
- Fixed Output Voltage 3.3 V
- Output Voltage Precision $\leq \pm 2\%$
- Output Current Capability up to 500 mA
- Ultra Low Current Consumption typ. 40 μA
- Very Low Dropout Voltage typ. 80 mV@100 mA
- Stable with Ceramic Output Capacitor of 1 μF
- Delayed Reset at Power-On: 16.5 ms
- Adjustable Reset Threshold down to 2.50 V
- Watchdog with fixed timing and current dependent deactivation: 96 ms, Activated at $I_Q > 5.5\text{ mA}$
- Enable, Undervoltage Reset, Overtemperature Shutdown
- Output Current Limitation
- Wide Temperature Range
- Green Product (RoHS compliant)
- AEC Qualified

Figure 1 PG-TO263-7

Functional Description

The TLS850F0TAV33 is a high performance very low dropout linear voltage regulator for 3.3 V supply in a PG-TO263-7 package.

With an input voltage range of 3 V to 40 V and very low quiescent of only 40 μ A, these regulators are perfectly suitable for automotive or any other supply systems connected to the battery permanently. The TLS850F0TAV33 provides an output voltage accuracy of 2 % and a maximum output current up to 500 mA.

The new loop concept combines fast regulation and very good stability while requiring only one small ceramic capacitor of 1 μ F at the output. At currents below 100 mA the device will have a very low typical dropout voltage of only 80 mV. The operating range starts already at input voltages of only 3 V (extended operating range). This makes the TLS850F0TAV33 also suitable to supply automotive systems that need to operate during cranking condition.

The device can be switched on and off by the Enable feature as described in [Chapter 5.5](#).

The output voltage is supervised by the Reset feature, including Undervoltage Reset, delayed Reset at Power-On and an adjustable lower Reset Threshold, more details can be found in [Chapter 5.7](#).

In addition, a Watchdog circuit with fixed timing is integrated to monitor the microcontroller's operation.

Internal protection features like output current limitation and overtemperature shutdown are implemented to protect the device against immediate damage due to failures like output short circuit to GND, over-current and over-temperatures.

Choosing External Components

An input capacitor C_I is recommended to compensate line influences. The output capacitor C_O is necessary for the stability of the regulating circuit. TLS850F0TAV33 is designed to be also stable with low ESR ceramic capacitors.

3 Pin Configuration

3.1 Pin Assignment TLS850F0TAV33

Figure 3 Pin Configuration

3.2 Pin Definitions and Functions TLS850F0TAV33

Pin	Symbol	Function
1	I	Input It is recommended to place a small ceramic capacitor (e.g. 100 nF) to GND, close to the IC terminals, in order to compensate line influences. See also Chapter 6.2.1
2	EN	Enable (integrated pull-down resistor) Enable the IC with high level input signal; Disable the IC with low level input signal;
3	RO/WO	Reset Output / Watchdog Output (intergrated pull-up resistor to Q) Open collector output; Leave open if the reset and watchdog function are not needed
4	GND	Ground
5	RADJ	Reset Threshold Adjustment Connect to GND to use standard value; Connect an external voltage divider to adjust reset threshold
6	WI	Watchdog Input (integrated pull-down resistor) Serve Watchdog with trigger input signal (usable for microcontroller monitoring)
7	Q	Output Voltage Connect output capacitor C_Q to GND close to the IC's terminals, respecting the values specified for its capacitance and ESR in "Functional Range" on Page 8
Heat Slug	–	Heat Slug Connect to heatsink area; Connect to GND

4 General Product Characteristics

4.1 Absolute Maximum Ratings

Table 1 Absolute Maximum Ratings¹⁾

$T_j = -40\text{ °C}$ to $+150\text{ °C}$; all voltages with respect to ground (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note / Test Condition	Number
		Min.	Typ.	Max.			
Input I, Enable EN							
Voltage	V_I, V_{EN}	-0.3	–	45	V	–	P_4.1.1
Output Q, Reset/Watchdog Output RO/WO							
Voltage	$V_Q, V_{RO/WO}$	-0.3	–	7	V	–	P_4.1.3
Watchdog Input WI, Reset Threshold Adjustment RADJ							
Voltage	V_{WI}, V_{RADJ}	-0.3	–	7	V	–	P_4.1.5
Temperatures							
Junction Temperature	T_j	-40	–	150	°C	–	P_4.1.7
Storage Temperature	T_{stg}	-55	–	150	°C	–	P_4.1.8
ESD Absorption							
ESD Susceptibility to GND	V_{ESD}	-2	–	2	kV	²⁾ HBM	P_4.1.9
ESD Susceptibility to GND	V_{ESD}	-500	–	500	V	³⁾ CDM	P_4.1.10
ESD Susceptibility Pin 1, 7 (corner pins) to GND	$V_{ESD1,7}$	-750	–	750	V	³⁾ CDM	P_4.1.12

1) Not subject to production test, specified by design.

2) ESD susceptibility, HBM according to ANSI/ESDA/JEDEC JS001 (1.5 kΩ, 100 pF)

3) ESD susceptibility, Charged Device Model “CDM” according JEDEC JESD22-C101

Note:

1. Stresses above the ones listed here may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
2. Integrated protection functions are designed to prevent IC destruction under fault conditions described in the data sheet. Fault conditions are considered as “outside” normal operating range. Protection functions are not designed for continuous repetitive operation.

4.2 Functional Range

Table 2 Functional Range
 $T_j = -40\text{ °C to }+150\text{ °C}$; all voltages with respect to ground (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note / Test Condition	Number
		Min.	Typ.	Max.			
Input Voltage Range	V_I	$V_{Q,nom} + V_{dr}$	–	40	V	¹⁾ –	P_4.2.1
Extended Input Voltage Range	$V_{I,ext}$	3.0	–	40	V	²⁾ –	P_4.2.3
Enable Voltage Range	V_{EN}	0	–	40	V	–	P_4.2.5
Output Capacitor's Requirements for Stability	C_Q	1	–	–	μF	³⁾⁴⁾ –	P_4.2.6
ESR	$ESR(C_Q)$	–	–	100	Ω	³⁾ –	P_4.2.7
Junction Temperature	T_j	-40	–	150	°C	–	P_4.2.9

1) Output current is limited internally and depends on the input voltage, see Electrical Characteristics for more details.

2) When V_I is between $V_{I,ext,min}$ and $V_{Q,nom} + V_{dr}$, $V_Q = V_I - V_{dr}$. When V_I is below $V_{I,ext,min}$, V_Q can drop down to 0 V.

3) Not subject to production test, specified by design.

4) The minimum output capacitance requirement is applicable for a worst case capacitance tolerance of 30%

Note: Within the functional or operating range, the IC operates as described in the circuit description. The electrical characteristics are specified within the conditions given in the Electrical Characteristics table.

4.3 Thermal Resistance

Note: This thermal data was generated in accordance with JEDEC JESD51 standards. For more information, go to www.jedec.org.

Table 3 Thermal Resistance

Parameter	Symbol	Values			Unit	Note / Test Condition	Number
		Min.	Typ.	Max.			
Package Version PG-TO263-7							
Junction to Case	R_{thJC}	–	3	–	K/W	¹⁾ –	P_4.3.6
Junction to Ambient	R_{thJA}	–	21	–	K/W	¹⁾²⁾ 2s2p board	P_4.3.7
Junction to Ambient	R_{thJA}	–	75	–	K/W	¹⁾³⁾ 1s0p board, footprint only	P_4.3.8
Junction to Ambient	R_{thJA}	–	42	–	K/W	¹⁾³⁾ 1s0p board, 300 mm ² heatsink area on PCB	P_4.3.9
Junction to Ambient	R_{thJA}	–	34	–	K/W	¹⁾³⁾ 1s0p board, 600 mm ² heatsink area on PCB	P_4.3.10

- 1) Not subject to production test, specified by design
- 2) Specified R_{thJA} value is according to Jedec JESD51-2,-5,-7 at natural convection on FR4 2s2p board; The Product (Chip+Package) was simulated on a 76.2 x 114.3 x 1.5 mm³ board with 2 inner copper layers (2 x 70μm Cu, 2 x 35μm Cu). Where applicable a thermal via array under the exposed pad contacted the first inner copper layer.
- 3) Specified R_{thJA} value is according to JEDEC JESD 51-3 at natural convection on FR4 1s0p board; The Product (Chip+Package) was simulated on a 76.2 x 114.3 x 1.5 mm³ board with 1 copper layer (1 x 70μm Cu).

5 Block Description and Electrical Characteristics

5.1 Voltage Regulation

The output voltage V_Q is divided by a resistor network. This fractional voltage is compared to an internal voltage reference and the pass transistor is driven accordingly.

The control loop stability depends on the output capacitor C_Q , the load current, the chip temperature and the internal circuit design. To ensure stable operation, the output capacitor's capacitance and its equivalent series resistor (ESR) requirements given in "Functional Range" on Page 8 have to be maintained. For details, also see the typical performance graph "Output Capacitor Series Resistor ESR(CQ) versus Output Current IQ" on Page 13. As the output capacitor also has to buffer load steps, it should be sized according to the application's needs.

An input capacitor C_I is recommended to compensate line influences. In order to block influences like pulses and HF distortion at input side, an additional reverse polarity protection diode and a combination of several capacitors for filtering should be used. Connect the capacitors close to the component's terminals.

In order to prevent overshoots during start-up, a smooth ramp up function is implemented. This ensures almost no output voltage overshoots during start-up, mostly independent from load and output capacitance.

Whenever the load current exceeds the specified limit, e.g. in case of a short circuit, the output current is limited and the output voltage decreases.

The overtemperature shutdown circuit prevents the IC from immediate destruction under fault conditions (e.g. output continuously short-circuit) by switching off the power stage. After the chip has cooled down, the regulator restarts. This leads to an oscillatory behavior of the output voltage until the fault is removed. However, junction temperatures above 150 °C are outside the maximum ratings and therefore significantly reduce the IC's lifetime.

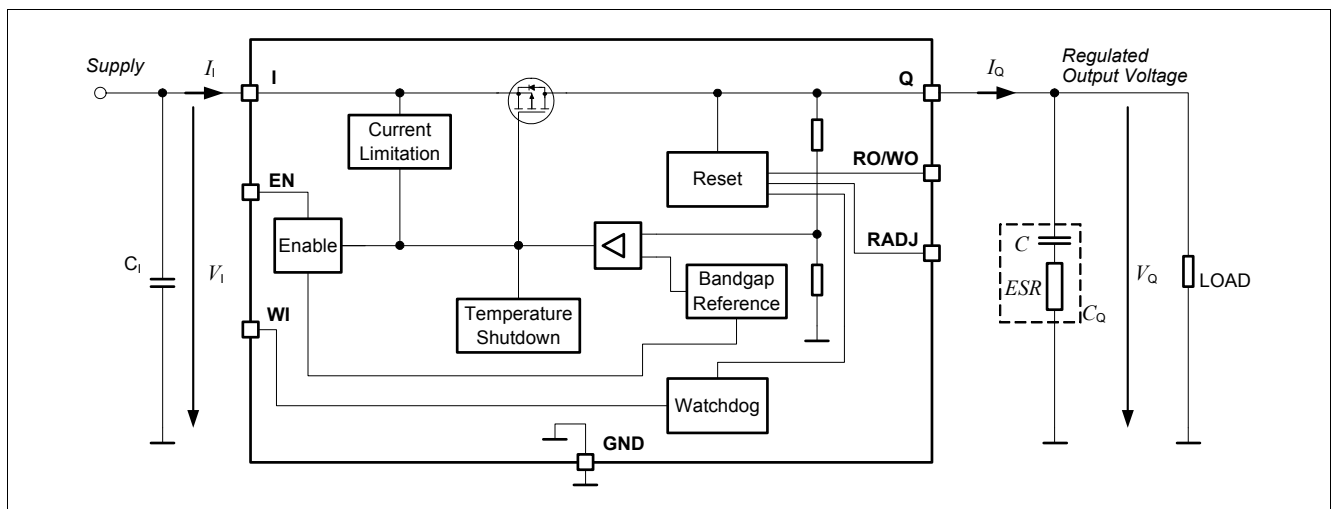

Figure 4 Voltage Regulation

Figure 5 Output Voltage vs. Input Voltage

Block Description and Electrical Characteristics

Table 4 Electrical Characteristics Voltage Regulator 3.3 V version

$T_j = -40\text{ °C}$ to $+150\text{ °C}$, $V_I = 13.5\text{ V}$, all voltages with respect to ground (unless otherwise specified)

5.5 Enable

The TLS850F0TAV33 can be switched on and off by the Enable feature: Connect a HIGH level as specified below (e.g. the battery voltage) to pin EN to enable the device; connect a LOW level as specified below (e.g. GND) to shut it down. The enable has a built in hysteresis to avoid toggling between ON/OFF state, if signals with slow slopes are applied to the EN input.

Table 6 Electrical Characteristics Enable

$T_j = -40\text{ °C}$ to $+150\text{ °C}$, $V_i = 13.5\text{ V}$, all voltages with respect to ground (unless otherwise specified)

5.7 Reset

The TLS850F0TAV33's output voltage is supervised by the Reset feature, including Undervoltage Reset, delayed Reset at Power-On and an adjustable Reset Threshold.

The Undervoltage Reset function sets the pin RO/WO to LOW, in case V_Q is falling for any reason below the Reset Threshold $V_{RT,low}$.

When the regulator is powered on, the pin RO/WO is held at LOW for the duration of the Power-On Reset Delay Time t_{rd} .

Figure 6 Block Diagram Reset Circuit

Reset Delay Time

The Reset Delay Time t_{rd} is fix defined according to Table 7.

Table 7 Reset DelayTime

Reset delay timing	t_{rd}
fix	16.5 ms

Power-On Reset Delay Time

The power-on reset delay time is defined by the parameter t_{rd} and allows a microcontroller and oscillator to start up. This delay time is the time period from exceeding the upper reset switching threshold $V_{RT,high}$ until the reset is released by switching the reset output “RO/WO” from “LOW” to “HIGH”.

Undervoltage Reset Delay Time

Unlike the power-on reset delay time, the undervoltage reset delay time is defined by the parameter t_{rd} and considers an output undervoltage event where the output voltage V_Q trigger the $V_{RT,low}$ threshold.

Reset Blanking Time

The reset blanking time $t_{tr,blank}$ avoids that short undervoltage spikes trigger an unwanted reset “low” signal.

Reset Reaction Time

In case the output voltage of the regulator drops below the output undervoltage lower reset threshold $V_{RT,low}$, the reset output “RO/WO” is set to low, after the delay of the internal reset reaction time $t_{rr,int}$. The reset blanking time $t_{rr,blank}$ is part of the reset reaction time $t_{rr,int}$.

Reset Output “RO/WO”

The reset output “RO/WO” is an open collector output with an integrated pull-up resistor. In case a lower-ohmic “RO/WO” signal is desired, an external pull-up resistor can be connected to the output “Q”. Since the maximum “RO/WO” sink current is limited, the minimum value of the optional external resistor “ $R_{RO/WO,ext}$ ” is given in [Table “Reset Output / Watchdog Output RO/WO” on Page 22](#).

Reset Output “RO/WO” Low for $V_Q \geq 1\text{ V}$

In case of an undervoltage reset condition reset output “RO/WO” is held “low” for $V_Q \geq 1\text{ V}$, even if the input voltage V_I is 0 V. This is achieved by supplying the reset circuit from the output capacitor.

Reset Adjust Function

The undervoltage reset switching threshold can be adjusted according to the application’s needs by connecting an external voltage divider ($R_{ADJ,1}$, $R_{ADJ,2}$) at pin “RADJ”. For selecting the default threshold connect pin “RADJ” to GND. The reset adjustment range for the TLS850F0TAV33 is given in [Reset Threshold Adjustment Range](#).

When dimensioning the voltage divider, take into consideration that there will be an additional current constantly flowing through the resistors.

With a voltage divider connected, the reset switching threshold $V_{RT,new}$ is calculated as follows (neglecting the Reset Adjust Pin Current I_{RADJ}):

$$V_{RT,lo,new} = V_{RADJ,th} \times (R_{ADJ,1} + R_{ADJ,2}) / R_{ADJ,2} \quad (1)$$

with

- $V_{RT,lo,new}$: Desired undervoltage reset switching threshold.
- $R_{ADJ,1}$, $R_{ADJ,2}$: Resistors of the external voltage divider, see [Figure 6](#).
- $V_{RADJ,th}$: Reset adjust switching threshold given in [Reset Adjustment Switching Threshold](#).

Internal Reset Reaction Time $t_{rr,int}$ versus Junction Temperature T_j

5.9 Standard Watchdog

The TLS850F0TAV33 features a load dependent watchdog function. The watchdog function monitors a microcontroller, including time base failures. In case of a missing falling edge within a certain pulse repetition time, the watchdog output “RO/WO” is set to “low”.

The watchdog uses an internal oscillator as timebase. The effective trigger window is derived from the watchdog timebase.

The watchdog output signal is provided by a combined Reset Output / Watchdog Output “RO/WO” pin.

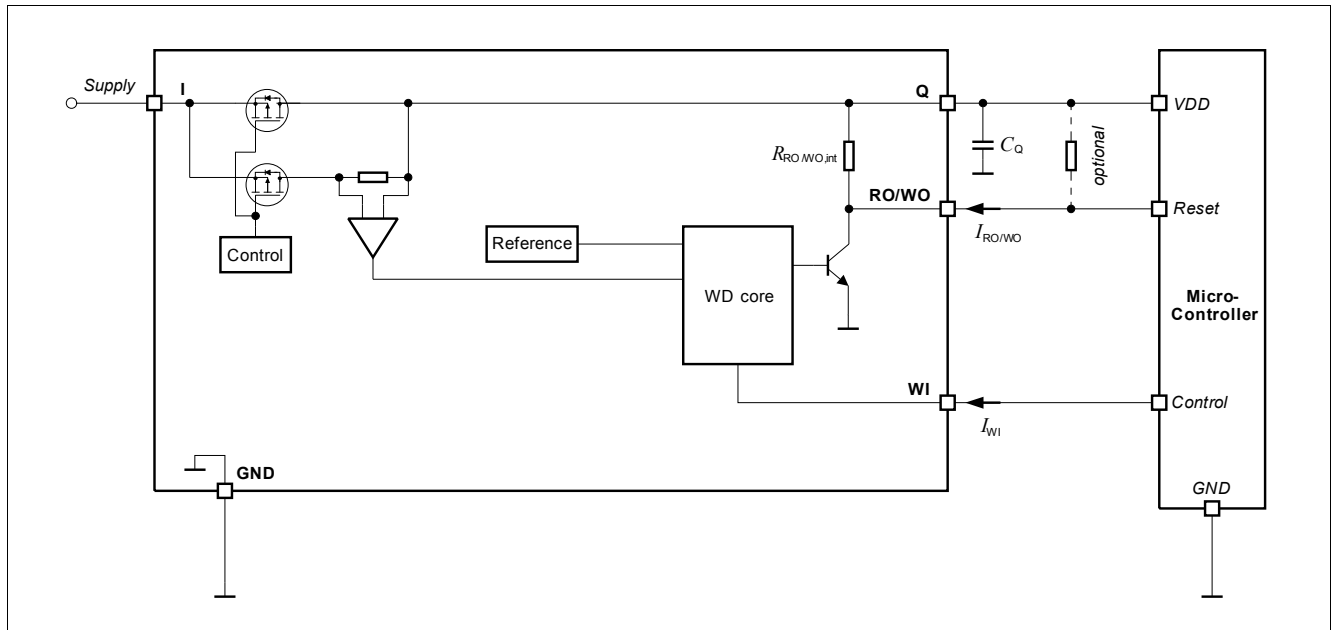

Figure 8 Block Diagram Watchdog Circuit

Watchdog Timing

Figure 9 shows the state diagram of the watchdog (WD) and the mode selection. After power-on, the reset output signal at the “RO/WO” pin (microcontroller reset) is kept LOW for the reset delay time t_{rd} . With the LOW to HIGH transition of the signal at “RO/WO” the device starts the watchdog ignore time $t_{WI,i}$. Next, the WD starts the watchdog trigger time (time frame within a trigger at WI must occur).

From now on, the timing of the signal on WI from the microcontroller must fit to the WD-trigger time $t_{WI,tr}$. A Re-Trigger of the WD-trigger time is done with a HIGH-to-LOW transient at the WI-pin within the active $t_{WI,tr}$.

Watchdog Output “RO/WO”

The watchdog output “RO/WO” is an open collector output with an integrated pull-up resistor. In case a lower-ohmic “RO/WO” signal is desired, an external pull-up resistor can be connected to the output “Q”. Since the maximum “RO/WO” sink current is limited, the minimum value of the optional external resistor “ $R_{RO/WO,ext}$ ” is given in Table “Reset Output / Watchdog Output RO/WO” on Page 22. A HIGH to LOW transition of the watchdog trigger signal on pin WI is taken as a trigger. A watchdog signal is generated (“RO/WO” goes LOW), if there is no trigger pulse during the Watchdog trigger time.

Block Description and Electrical Characteristics

Figure 9 Typical Watchdog Timing Diagram, Watchdog and Reset Modes

Watchdog Input “WI”

The watchdog is triggered by a falling edge at the watchdog input pin “WI”. The amplitude and slope of this signal has to comply with the specification (Table “Watchdog Input WI” on Page 26). For details regarding test pulses, see Figure 10 “Test Pulses Watchdog Input WI” on Page 25.

Watchdog Trigger Time

The Watchdog Trigger Time $t_{WI,tr}$ is fixed to a static value according to [Table 10](#).

Table 10 Watchdog Trigger Time

Watchdog trigger timing	$t_{WI,tr,typ}$
fix to	96 ms

Watchdog deactivation by current control

The Watchdog is load dependent inactive. This ensures, that if the microcontroller is in a power save mode ($I_Q \leq I_{Q,W,deact}$) and not able to provide a correct watchdog trigger signal at pin “WI”, no watchdog signal “RO/WO = low” is generated. The transition from an active to an inactive state will be performed after a dead time of $t_{W,IQ,filter,max}$, when output current keeps below the deactivation threshold. This protects against an unintended entering of the watchdog deactivation state caused by short dynamic current drops. In case of very short current drops up to the time of $t_{W,IQ,filter,min}$, the activation state will definitely be kept. These scenarios are also valid for the transition from deactivation to activation state. For details see also

Figure 11 Watchdog Output behavior for Watchdog deactivation by current control

Scenario “A”

In scenario “A” the watchdog logic expects a next trigger at WI pin within the WD-trigger time $t_{WI,tr}$. This state is interrupted by the low current load state ($I_Q \leq I_{Q,W,deact}$). During this state, the watchdog is disabled. The watchdog output signal “RO/WO” will stay high while the watchdog is disabled. After leaving the low current load state ($I_Q \geq I_{Q,W,act}$), an ignore window $t_{WI,i}$ follows. After this, the watchdog trigger time $t_{WI,tr}$ starts. This behavior is defined for cases with a low current load time greater than $t_{WO,low}$.

Scenario “B”

In scenario “B” the watchdog is not served within WD-trigger time $t_{WI,tr}$ with a trigger event at WI pin. As a result the “RO/WO” is set to low. This state is interrupted by the low current load state ($I_Q \leq I_{Q,W,deact}$). During this state, the watchdog is disabled. The watchdog output signal “RO/WO” is kept in low state for $t_{WO,low}$ and then the “RO/WO” is set to high. After leaving the low current load state ($I_Q \geq I_{Q,W,act}$), an ignore window $t_{WI,i}$ follows. After this, the watchdog trigger time $t_{WI,tr}$ starts. This behavior is defined for cases with a low current load time greater than $t_{WO,low}$.

Scenario “C”

In scenario “C” the watchdog is not served within WD-trigger time $t_{WI,tr}$ with a trigger event at WI pin. As a result the “RO/WO” is set to low. After this an ignore window follows. This state is interrupted by the low current load state ($I_Q \leq I_{Q,W,deact}$). During this state, the watchdog is disabled. The watchdog output signal “RO/WO” will stay high while the watchdog is disabled. After leaving the low current load state ($I_Q \geq I_{Q,W,act}$), an ignore window $t_{WI,i}$ follows. After this, the watchdog trigger time $t_{WI,tr}$ starts. This behavior is defined for cases with a low current load time greater than $t_{WO,low}$.

Scenario “D”

In scenario “D” the watchdog is not served within WD-trigger time $t_{WI,tr}$ with a trigger event at WI pin. As a result the “RO/WO” is set to low. This state is interrupted by the low current load state ($I_Q \leq I_{Q,W,deact}$). During this state, the watchdog is disabled. The watchdog output signal “RO/WO” is kept in low state for the time of low current load state. After leaving the low current load state ($I_Q \geq I_{Q,W,act}$), an ignore window $t_{WI,i}$ follows. After this, the watchdog trigger time $t_{WI,tr}$ starts. This behavior is defined for cases with a low current load time less than $t_{WO,low}$.

Watchdog deactivation by external signal (pin “WI”)

Note: Disabling the watchdog should only be considered when the application is not running in the normal operating conditions as the safe operation is not ensured any more. Example would be the flashing process of the microcontroller.

The Watchdog can be disabled by connecting a voltage level between the range of 1.15 V to 1.40 V to WI. By entering the Watchdog deactivation, the “RO/WO” signal behaves like it is described in . The transition from active to an inactive state will be performed after a dead time of $t_{WI,filter,max}$, when correct level to WI pin is applied. This protects against the unintended entering of watchdog deactivation state. After leaving the deactivation voltage range 1.15 V to 1.40 V, the Watchdog is again active and starts with an ignore window. This scenario is also valid for the transition from deactivation to activation state.

Figure 12 Watchdog Output behavior for Watchdog deactivation by WI pin

Scenario "A"

In scenario "A" the watchdog logic expects a next trigger at WI pin within the WD-trigger time $t_{WI,tr}$. This state is interrupted by setting V_{WI} to the disable condition ($V_{WI,dis,low} \leq V_{WI} \leq V_{WI,dis,high}$). During this state, the watchdog is disabled. The watchdog output signal "RO/WO" will stay high while the watchdog is disabled. After leaving the disable condition ($V_{WI} \geq V_{WI,dis,high}$ or $V_{WI} \leq V_{WI,dis,low}$), an ignore window $t_{WI,i}$ follows. After this, the watchdog trigger time $t_{WI,tr}$ starts. This behavior is defined for cases with a low current load time greater than $t_{WO,low}$.

Scenario "B"

In scenario "B" the watchdog is not served within WD-trigger time $t_{WI,tr}$ with a trigger event at WI pin. As a result the "RO/WO" is set to low. This state is interrupted by setting V_{WI} to the disable condition ($V_{WI,dis,low} \leq V_{WI} \leq V_{WI,dis,high}$). During this state, the watchdog is disabled. The watchdog output signal "RO/WO" is kept in low state for $t_{WO,low}$ and then the "RO/WO" is set to high. After leaving the disable condition ($V_{WI} \geq V_{WI,dis,high}$ or $V_{WI} \leq V_{WI,dis,low}$), an ignore window $t_{WI,i}$ follows. After this, the watchdog trigger time $t_{WI,tr}$ starts. This behavior is defined for cases with a low current load time greater than $t_{WO,low}$.

Scenario "C"

In scenario "C" the watchdog is not served within WD-trigger time $t_{WI,tr}$ with a trigger event at WI pin. As a result the "RO/WO" is set to low. After this an ignore window follows. This state is interrupted by setting V_{WI} to the disable condition ($V_{WI,dis,low} \leq V_{WI} \leq V_{WI,dis,high}$). During this state, the watchdog is disabled. The watchdog output signal "RO/WO" will stay high while the watchdog is disabled. After leaving the disable condition ($V_{WI} \geq V_{WI,dis,high}$ or $V_{WI} \leq V_{WI,dis,low}$), an ignore window $t_{WI,i}$ follows. After this, the watchdog trigger time $t_{WI,tr}$ starts. This behavior is defined for cases with a low current load time greater than $t_{WO,low}$.

Scenario "D"

In scenario "D" the watchdog is not served within WD-trigger time $t_{WI,tr}$ with a trigger event at WI pin. As a result the "RO/WO" is set to low. This state is interrupted by setting V_{WI} to the disable condition ($V_{WI,dis,low} \leq V_{WI} \leq V_{WI,dis,high}$). During this state, the watchdog is disabled. The watchdog output signal "RO/WO" is kept in low state for the time of low current load state. After leaving the disable condition ($V_{WI} \geq V_{WI,dis,high}$ or $V_{WI} \leq V_{WI,dis,low}$), an ignore window $t_{WI,i}$ follows. After this, the watchdog trigger time $t_{WI,tr}$ starts. This behavior is defined for cases with a low current load time less than $t_{WO,low}$.

5.10 Typical Performance Characteristics Standard Watchdog

Typical Performance Characteristics

Watchdog Trigger Time $t_{WI,tr}$ versus Junction Temperature T_j

Watchdog Output Low Time $t_{WO,low}$ versus Junction Temperature T_j

Watchdog Activation/Deactivation Current $I_{Q,W,act}$, $I_{Q,W,deact}$ versus Junction Temperature T_j

Watchdog Disable $V_{WI,dis}$ Threshold versus Junction Temperature T_j

6 Application Information

6.1 Application Diagram

Note: The following information is given as a hint for the implementation of the device only and shall not be regarded as a description or warranty of a certain functionality, condition or quality of the device.

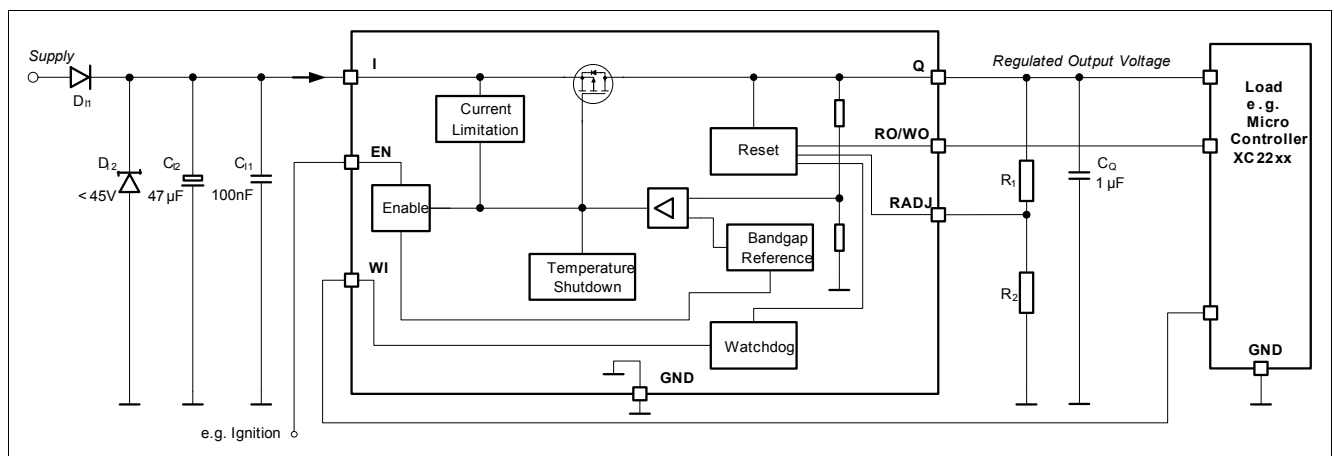

Figure 13 Application Diagram

Note: This is a very simplified example of an application circuit. The function must be verified in the real application.

6.2 Selection of External Components

6.2.1 Input Pin

The typical input circuitry for a linear voltage regulator is shown in the application diagram above.

A ceramic capacitor at the input, in the range of 100 nF to 470 nF, is recommended to filter out the high frequency disturbances imposed by the line e.g. ISO pulses 3a/b. This capacitor must be placed very close to the input pin of the linear voltage regulator on the PCB.

An aluminum electrolytic capacitor in the range of 10 μF to 470 μF is recommended as an input buffer to smooth out high energy pulses, such as ISO pulse 2a. This capacitor should be placed close to the input pin of the linear voltage regulator on the PCB.

An overvoltage suppressor diode can be used to further suppress any high voltage beyond the maximum rating of the linear voltage regulator and protect the device against any damage due to over-voltage.

The external components at the input are not mandatory for the operation of the voltage regulator, but they are recommended in case of possible external disturbances.

6.2.2 Output Pin

An output capacitor is mandatory for the stability of linear voltage regulators.

The requirement to the output capacitor is given in [“Functional Range” on Page 8](#). The graph [“Output Capacitor Series Resistor ESR\(CQ\) versus Output Current IQ” on Page 13](#) shows the stable operation range of the device.

TLS850F0TAV33 is designed to be also stable with low ESR capacitors. According to the automotive requirements, ceramic capacitors with X5R or X7R dielectrics are recommended.

The output capacitor should be placed as close as possible to the regulator's output and GND pins and on the same side of the PCB as the regulator itself.

In case of rapid transients of input voltage or load current, the capacitance should be dimensioned in accordance and verified in the real application that the output stability requirements are fulfilled.

6.3 Thermal Considerations

Knowing the input voltage, the output voltage and the load profile of the application, the total power dissipation can be calculated:

$$P_D = (V_I - V_Q) \times I_Q + V_I \times I_q \quad (2)$$

with

- P_D : continuous power dissipation
- V_I : input voltage
- V_Q : output voltage
- I_Q : output current
- I_q : quiescent current

The maximum acceptable thermal resistance R_{thJA} can then be calculated:

$$R_{thJA,max} = (T_{j,max} - T_a) / P_D \quad (3)$$

with

- $T_{j,max}$: maximum allowed junction temperature
- T_a : ambient temperature

Based on the above calculation the proper PCB type and the necessary heat sink area can be determined with reference to the specification in **[“Thermal Resistance” on Page 9](#)**.

Example

Application conditions:

$$V_I = 13.5 \text{ V}$$

$$V_Q = 3.3 \text{ V}$$

$$I_Q = 175 \text{ mA}$$

$$T_a = 85 \text{ °C}$$

Calculation of $R_{thJA,max}$:

$$\begin{aligned} P_D &= (V_I - V_Q) \times I_Q + V_I \times I_q && (V_I \times I_q \text{ can be neglected because of very low } I_q) \\ &= (13.5 \text{ V} - 3.3 \text{ V}) \times 175 \text{ mA} \\ &= 1.785 \text{ W} \end{aligned}$$

$$\begin{aligned} R_{thJA,max} &= (T_{j,max} - T_a) / P_D \\ &= (150 \text{ °C} - 85 \text{ °C}) / 1.785 \text{ W} = 36.41 \text{ K/W} \end{aligned}$$

As a result, the PCB design must ensure a thermal resistance R_{thJA} lower than 36.41 K/W. According to “**Thermal Resistance**” on Page 9, at least 600 mm² heatsink area is needed on the FR4 1s0p PCB, or the FR4 2s2p board can be used to ensure a proper cooling for the TLS850F0TAV33 in package.

6.4 Reverse Polarity Protection

TLS850F0TAV33 is not self protected against reverse polarity faults and must be protected by external components against negative supply voltage. An external reverse polarity diode is needed. The absolute maximum ratings of the device as specified in “**Absolute Maximum Ratings**” on Page 7 must be kept.

6.5 Further Application Information

7 Package Outlines

Figure 14 PG-TO263-7

Green Product (RoHS compliant)

To meet the world-wide customer requirements for environmentally friendly products and to be compliant with government regulations the device is available as a green product. Green products are RoHS-Compliant (i.e Pb-free finish on leads and suitable for Pb-free soldering according to IPC/JEDEC J-STD-020).
