# 1 Introduction

The MWPR1x24 is a wireless power receiver controller with integrated Bluetooth® Low Energy ver. 4.2 compliant transceiver. The wireless power receiver controller measures the current and voltage of the power output of the wireless power system and transmits the values via Bluetooth LE to wireless power transmitter controller which controls the power transfer.

The key characteristics and features of the system are:

- Enables single or multi-coil power transmitter topology.
- Variable Z-gap range (vertical movement) from 4 mm to 35 mm – depends on coils setup. This range is limited by the 65-W power transfer programmable thresholds.
- Modularity in design of power transmitter unit to extend the number of transmitter coils to form a larger active area, which requires:
  - Minor reconfiguration of software.
  - Extension of the multiplexer hardware (coil switches and control signal multiplexer).
  - No major impact on the system topology.
- Fast wireless power transfer start-up time below 2.5 s (applicable for up to seven transmitter coils).
- No power from powered device is needed for the power receiver unit to start-up.
- Support of one Power Class 1 (PC1) device with up to 65 W of PRU output. Premium version support also one Qi-certified Power Class 0 (PC0) device with support for 5-W and 15-W receivers.
- Peak power transfer efficiency (input of power transmitter unit to output of power receiver unit) of over 86 % at the best coil placement and 65 W of power receiver unit output.
- Power receiver unit output-integrated protections for over-power and over-current scenarios.
- Run-time system resonant frequency tracking ranging from 100 kHz to 145 kHz to improve the power-transfer efficiency.
- The power receiver unit power output acts as a constant 19.5-V source, forming an alternative to standard 65-W (or lower) AC power adapters, and thus simplifying its integration into the target system. Output voltage is adjustable.
- Foreign Object Detection during and prior to the power transfer.
- Interface for Bluetooth Low Energy (Bluetooth LE) out-band communication between the power receiver unit and power transmitter unit for secured data and firmware update transfer towards the power transmitter unit.

- The power receiver unit is enabled with authentication devices to ensure that only safe and authentic devices initiate the power transfer in premium version.
- Compliance with the EMC regulation for commercial electronic devices.
- The wireless communication link represents proprietary system which is not opened to the end user.

## 4.3 Transceiver Functions

### Receive

The receiver architecture is Zero IF (ZIF) where the received signal after passing through RF front end is down-converted to a baseband signal. The signal is filtered and amplified before it is fed to analog-to-digital converter. The digital signal is then decimated to a baseband clock frequency before it is digitally processed, demodulated and passed on to packet processing/link-layer processing.

### Transmit

The transmitter transmits O-QPSK or GFSK/FSK modulation having power and channel selection adjustment per user application. After the channel of operation is determined, coarse and fine tuning is executed within the Frac-N PLL to engage signal lock. After signal lock is established, the modulated buffered signal is then routed to a multi-stage amplifier for transmission. The differential signals at the output of the PA (RF\_P, RF\_N) are converted to a single ended(SE) output signal by an on-chip balun.

## 6 System and Power Management

### 6.1 Power Management

The MWPR1x24 includes internal power management features that can be used to control the power usage. The power management of the MWPR1x24 includes power management controller (PMC) and a DC-DC converter which can operate in a buck, boost or bypass configuration. The PMC is designed such that the RF radio will

remain in state-retention while the core is in various stop modes. It can make sure the device can stay in low current consumption mode while the RF radio can wakeup quick enough for communication.

### 6.1.1 DC-DC Converter

The features of the DC-DC converter include the following:

- Single inductor, multiple outputs.
- Boost mode (pin selectable; CFG=GND).
- Buck mode (pin selectable; CFG=VDCDC\_IN).
- Continuous or pulsed operation (hardware/software configurable).
- Power switch input to allow external control of power up, and to select bypass mode.
- Output signal to indicate power stable. Purpose is for the rest of the chip to be used as a POR.
- Scaled battery output voltage suitable for SAR ADC utilization.
- Internal oscillator for support when the reference oscillator is not present.
- 1.8 V output is capable of supplying the external device a maximum of 38.9 mA (VDD\_1P8OUT = 1.8 V, VDCDC\_IN = 3.0 V) and 20.9 mA (VDD\_1P8OUT = 3.0 V, VDCDC\_IN = 3.0 V), with MCU in RUN mode, peripherals are disabled.

## 6.2 Modes of Operation

The Arm Cortex-M0+ core in the MWPR1x24 has three primary modes of operation: Run, Wait, and Stop modes. For each run mode, there is a corresponding wait and stop mode. Wait modes are similar to Arm sleep modes. Stop modes are similar to Arm deep sleep modes. The very low power run (VLPR) operation mode can drastically reduce runtime power when the maximum bus frequency is not required to handle the application needs.

The WFI instruction invokes both wait and stop modes. The primary modes are augmented in a number of ways to provide lower power based on application needs.

### 6.2.1 Power modes

The power management controller (PMC) provides multiple power options to allow the user to optimize power consumption for the level of functionality needed.

Depending on the stop requirements of the user application, a variety of stop modes are available that provide state retention, partial power down or full power down of certain logic and/or memory. I/O states are held in all modes of operation. The following table compares the various power modes available.

For each run mode there is a corresponding wait and stop mode. Wait modes are similar to Arm sleep modes. Stop modes (VLPS, STOP) are similar to Arm sleep deep mode. The very low power run (VLPR) operating mode can drastically reduce runtime power when the maximum bus frequency is not required to handle the application needs.

The three primary modes of operation are run, wait and stop. The WFI instruction invokes either wait or stop depending on the SLEEPDEEP bit in Cortex-M0+ System Control Register. The primary modes are augmented in a number of ways to provide lower power based on application needs.

**Table 8. Power modes (At 25 deg C)**

Power mode	Description	CPU recovery method	Radio
Normal Run (all peripherals clock off)	Allows maximum performance of chip.	—	Radio can be active
Normal Wait - via WFI	Allows peripherals to function, while allowing CPU to go to sleep reducing power.	Interrupt	
Normal Stop - via WFI	Places chip in static state. Lowest power mode that retains all registers while maintaining LVD protection.	Interrupt	
PStop2 (Partial Stop 2)	Core and system clocks are gated. Bus clock remains active. Masters and slaves clocked by bus clock remain in Run or VLPRun mode. The clock generators in MCG and the on-chip regulator in the PMC also remain in Run or VLPRun mode.	Interrupt	
PStop1 (Partial Stop 1)	Core, system clocks and bus clock are gated. All bus masters and slaves enter Stop mode. The clock generators in MCG and the on-chip regulator in the PMC also remain in Run or VLPRun mode.	Interrupt	
VLPR (Very Low Power Run) (all peripherals off)	Reduced frequency (1MHz) Flash access mode, regulator in low power mode, LVD off. Internal oscillator can provide low power 4 MHz source for core. (Values @2MHz core/ 1MHz bus and flash, module off, execution from flash).  Biasing is disabled when DC-DC is configured for continuous mode in VLPR/W	—	Radio operation is possible only when DC-DC is configured for continuous mode. <sup>1</sup> However, there may be insufficient MIPS with a 4MHz MCU to support much in the way of radio operation.
VLPR (Very Low Power Wait) - via WFI (all peripherals off)	Similar to VLPR, with CPU in sleep to further reduce power. (Values @4MHz core/ 1MHz bus, module off)	Interrupt

Disable all analog modules in PMC and retains I/O state and DGO state. LPO disabled, POR brown-out detection enabled, Pin interrupt only. Radio logic is power gated.	Wakeup Reset	Radio operation not supported. The Radio digital is power-gated in VLLS1/0
VLLS0 (Very Low Leakage Stop0) without Brown-out Detection	VLLS0 is not supported with DC-DC buck/boost configuration but is supported with bypass configuration  The 32-byte system register file remains powered for customer-critical data. Disable all analog modules in PMC and retains I/O state and DGO state. LPO disabled, POR brown-out detection disabled, Pin interrupt only. Radio logic is power gated.	Wakeup Reset	

1. Biasing is disabled, but the flash is in a low power mode for VLPx, so this configuration can realize some power savings over use of Run/Wait/Stop

- Open drain outputs must be pulled to  $V_{DD}$ .

## 7.2.4 Power mode transition operating behaviors

All specifications except t<sub>POR</sub> and VLLS<sub>x</sub>→RUN recovery times in the following table assume this clock configuration:

- CPU and system clocks = 48 MHz
- Bus and flash clock = 24 MHz
- FEI clock mode

POR and VLLS<sub>x</sub>→RUN recovery use FEI clock mode at the default CPU and system frequency of 21 MHz, and a bus and flash clock frequency of 10.5 MHz.

1. Normal boot (FTFA\_FOPT[LPBOOT]=11). When the DC-DC converter is in bypass mode, TPOR will not meet the 300μs spec when 1) VDD\_1P5 < 1.6V at 25°C and °C. 2) 1.5V ≤ VDD\_1P5 ≤ 1.8V. For the bypass mode special case where VDD\_1P5 = VDD\_1P8, TPOR did not meet the 300μs maximum spec when the supply slew rate ≤ 100V/s.

5. These typical values listed are with the slow internal reference clock (FEI) using factory trim and DMX32 = 1.
6. The resulting clock frequency must not exceed the maximum specified clock frequency of the device.
7. This specification is based on standard deviation (RMS) of period or frequency.
8. This specification applies to any time the FLL reference source or reference divider is changed, trim value is changed, DMX32 bit is changed, DRS bits are changed, or changing from FLL disabled (BLPE, BLPI) to FLL enabled (FEI, FEE, FBE, FBI). If a crystal/resonator is being used as the reference, this specification assumes it is already running.

### 7.5.3.2 Reference Oscillator Specification

The MWPR1x24 has been designed to meet targeted specifications with a +/-20 ppm frequency error over the life of the part, which includes the temperature, mechanical and aging effects.

The table below lists the recommended crystal specifications. Note that these are recommendations only and deviation may be allowed. However, deviations may result in degraded RF performance or possibly a failure to meet RF protocol certification standards. Designers must ensure that the crystal(s) they use will meet the requirements of their application.

- All accuracy numbers assume the ADC is calibrated with  $V_{REFH} = V_{DDA}$ .
- Typical values assume  $V_{DDA} = 3.0$  V, Temp = 25 °C,  $f_{ADCK} = 2.0$  MHz unless otherwise stated. Typical values are for reference only and are not tested in production.
- The ADC supply current depends on the ADC conversion clock speed, conversion rate and ADC\_CFG1[ADLPC] (low power). For lowest power operation, ADC\_CFG1[ADLPC] must be set, the ADC\_CFG2[ADHSC] bit must be clear with 1 MHz ADC conversion clock speed.
- 1 LSB =  $(V_{REFH} - V_{REFL})/2^N$ .

- $V_{REFH}$  = Output of Voltage Reference(VREF).
- Input data is 100 Hz sine wave. ADC conversion clock < 12 MHz.

Data set-up time	t <sub>SU</sub> ; DAT	250 <sup>4</sup>	—	100 <sup>2, 5</sup>	—	ns
Rise time of SDA and SCL signals	t <sub>r</sub>	—	1000	20 + 0.1C <sub>b</sub> <sup>6</sup>	300	ns
Fall time of SDA and SCL signals	t <sub>f</sub>	—	300	20 + 0.1C <sub>b</sub> <sup>5</sup>	300	ns
Set-up time for STOP condition	t <sub>SU</sub> ; STO	4	—	0.6	—	µs

Pulse width of spikes that must be suppressed by the input filter	t <sub>SP</sub>	N/A	N/A	0	50	ns

1. The master mode I<sup>2</sup>C deasserts ACK of an address byte simultaneously with the falling edge of SCL. If no slaves acknowledge this address byte, then a negative hold time can result, depending on the edge rates of the SDA and SCL lines.
2. The maximum t<sub>HD</sub>; DAT must be met only if the device does not stretch the LOW period (t<sub>LOW</sub>) of the SCL signal.
3. Input signal Slew = 10 ns and Output Load = 50 pF.
4. Set-up time in slave-transmitter mode is 1 IP Bus clock period, if the TX FIFO is empty.
5. A Fast mode I<sup>2</sup>C bus device can be used in a Standard mode I<sup>2</sup>C bus system, but the requirement t<sub>SU</sub>; DAT ≥ 250 ns must then be met. This is automatically the case if the device does not stretch the LOW period of the SCL signal. If such

a device does stretch the LOW period of the SCL signal, then it must output the next data bit to the SDA line  $t_{rmax} + t_{SU};_{DAT} = 1000 + 250 = 1250$  ns (according to the Standard mode I<sup>2</sup>C bus specification) before the SCL line is released.

6.  $C_b$  = total capacitance of the one bus line in pF.

1. This is the steady state DC output power. It requires VDCDC\_IN >= 1.7V in boost mode. Excessive transient current load from external device will cause 1p8V and 1P5 output voltage unregulated temporary.
2. This is the frequency that will be observed at LN and LP pins.
3. The voltage output level can be controlled by programming DCDC\_VDD1P8CTRL\_TRG field in DCDC\_REG3.
4. The output current specification in both buck and boost modes represents the maximum current the DC-DC converter can deliver. The MWPR1x24 radio and MCU blocks current consumption is not excluded. Note that the maximum output power of the DC-DC converter is 125mW. The available supply current for external device depends on the energy consumed by the internal peripherals in MWPR1x24.
5. When using DC-DC in low power mode(pulsed mode), current load must be less than 0.5 mA.
6. The minimum VDD\_1P5\_boost is the maximum of either what is programmed using DCDC\_VDD1P5CTRL\_TRG\_BOOST field in DCDC\_REG3 or VDCDC\_IN\_boost + 0.05V. For example, if VDCDC\_IN = 0.9V, minimum VDD\_1P5 is as programmed in DCDC\_VDD1P5CTRL\_TRG\_BOOST. If VDCDC\_IN = 1.5V, minimum VDD\_1P5 = 1.5 + 0.05V is 1.55V.
7. 1.8 V is the default value of the DC-DC 1.5 V output voltage in boost mode. The user can program DCDC\_VDD1P5CTRL\_TRG\_BOOST field in register DCDC\_REG3 to control 1.5 V output voltage level. For reliable radio operation, a voltage level of 1.425 V is required. VDD\_1P5 must not be programmed higher than VDD\_1P8.
8. 1.5 V is intended to supply power to MWPR1x24 only. It is not designed to supply power to an external device.
9. Turn on time is measured from the application of power (to DCDC\_IN) to when the DCDC\_REG0[DCDC\_STS\_DC\_OK] bit is set. Code execution may begin before the DCDC\_REG0[DCDC\_STS\_DC\_OK] bit is set. Full device specification is not guaranteed until the bit sets.
10. In Buck mode, the maximum VDD\_1P8 output is the minimum of either VDCDC\_IN\_BUCK minus 50 mV or 3.5 V. For example, if VDCDC\_IN = 1.85V, maximum VDD\_1P8 is 1.8V. If VDCDC\_IN = 4.2V, maximum VDD\_1P8 is 3V.
11. 1.5 V is the default value of DCDC VDD\_1P5 in buck mode. The user can program DCDC\_VDD1P5CTRL\_TRG\_BUCK field in register DCDC\_REG3 to control 1P5 output voltage level. For Radio operation, minimum 1.425 V is required. VDD\_1P5 must not be programmed higher than VDD\_1P8.
