

# NCN6004A

## Dual SAM/SIM Interface Integrated Circuit

The NCN6004A is an interface IC dedicated for Secured Access Module reader/writer applications. It allows the management of two external ISO/EMV cards thanks to a simple and flexible microcontroller interface. Several NCN6004A interfaces can share a single data bus, assuming the external MPU provides the right Chip Select signals to identify each IC connected on the bus. A built in accurate protection system guarantees timely and controlled shutdown in the case of external error conditions.

On top of that, the NCN6004A can independently handle the power supply, in the range 2.7 V to 5.0 V input voltage, provided to each external Smart Card. The interface monitors the current flowing into each Smart Card, a flag being set in the case of overload.

### Features

- Separated, Built-in DC/DC Converters Supply  $V_{CC}$  Power to External Cards
- 100% Compatible with ISO 7816-3, EMV and GIE-CB Standards
- Fully GSM Compliant
- Individually Programmable ISO/EMV Clock Generator
- Built-in Programmable CRD\_CLK Stop Function Handles Run or High/Low State
- Programmable CRD\_CLK Slopes to Cope with Wide Operating Frequency Range
- Programmable Independent  $V_{CC}$  Supply for Each Smart Card
- Support up to 65 mA  $V_{CC}$  Supply to Each ISO/EMV Card
- Multiple NCN6004A Parallel Operation on a Shared Bus
- 8 kV/Human Model ESD Protection on Each Interface Pin
- Provides C4/C8 Channels
- Provides 1.8 V, 3.0 V or 5.0 V Card Supply Voltages
- Pb-Free Package is Available\*

### Typical Applications

- Set Top Box Decoder
- ATM Multi Systems, POS, Handheld Terminals
- Internet E-commerce PC Interface
- Multiple Self Serve Automatic Machines
- Wireless Phone Payment Interface
- Automotive Operating Time Controller

## PIN DESCRIPTION

Pin	Symbol	Type	Description
1	A0	INPUT	This pin is combined with $\overline{CS}$ , A1, A2, A3, CARD_SEL and $\overline{PGM}$ to program the chip mode of operation, the CRD_VCC voltage value, and to read the data provided by the internal STATUS register (Table 1).
2	A1	INPUT	This pin is combined with $\overline{CS}$ , A0, A2, A3, CARD_SEL and $\overline{PGM}$ to program the chip mode of operation, the CRD_VCC voltage value, and to read the data provided by the internal STATUS register (Table 1).
3	A2	INPUT	This pin is combined with $\overline{CS}$ , A0, A1, A3, CARD_SEL and $\overline{PGM}$ to program the chip mode of operation, the CRD_VCC voltage value, and to read the data provided by the internal STATUS register (Table 1).
4	A3	INPUT	This pin is combined with $\overline{CS}$ , A0, A1, A2, CARD_SEL and $\overline{PGM}$ to program the chip mode of operation, the CRD_VCC voltage value, and to read the data provided by the internal STATUS register (Table 1).
5	CARD_SEL	INPUT	This pin provides logic identification of the Card #A/Card #B external smart card. The logic signal is set up by the external microcontroller. CARD_SEL = High → selection of the Smart Card A connected to pins 20, 21, 22, 23, 24, 29 and 30 (respectively CRD_DET_A, CRD_C8_A, CRD_C4_A, CRD_RST_A, CRD_IO_A, CRD_VCC_A and CRD_CLK_A). CARD_SEL = Low → selection of the Smart Card B connected to pins 41, 39, 40, 31, 38, 37, and 32 (respectively CRD_DET_B, CRD_C4_B, CRD_C8_B, CRD_CLK_B, CRD_RST_B, CRD_IO_B, and CRD_VCC_B).
6	$\overline{PGM}$	DIGITAL INPUT	This pin is combined with $\overline{CS}$ , A0, A1, A2, A3, and CARD_SEL to program the chip mode of operation and to read the data provided by the internal STATUS register (Figure 4 and Table 1). $\overline{PGM}$ = H → the NCN6004A is under normal operation and all the data with the external card can be exchanged using any of the Smart Card A or Smart Card B Lines $\overline{PGM}$ = Low → the NCN6004A runs the programming mode and related parameters can be re programmed according to a given need. In this case, the related card side logic signals are latched in their previous states and no transaction can occurs. The programmed states are latched upon the $\overline{PGM}$ rising slope (Figure 4).
7	$\overline{CS}$	DIGITAL INPUT	This pin provides the Chip Select Function for the NCN6004A device. $\overline{CS}$ = High → Pins A0, A1, A2, A3, CARD_SEL, $\overline{PGM}$ , PWR_ON, RESET_A, RESET_B, C4_A, C4_B, C8_A, C8_B, I/O_A and I/O_B are disabled, the pre activated CRD_VCC maintains it's currently programmed value. $\overline{CS}$ = Low → Pins A0, A1, A2, A3, CARD_SEL, $\overline{PGM}$ , PWR_ON, RESET_A, RESET_B, C4_A, C4_B, C8_A, C8_B, I/O_A and I/O_B are activated, all the functions being available. An internal pull up resistor, connected to V <sub>CC</sub> , provides a logic bias when the external $\mu$ P is in the high impedance state.
8	PWR_ON	DIGITAL INPUT	This pin activates or deactivates the DC/DC converter selected by CARD_SEL upon positive/negative going transient. PWR_ON = Positive going High → DC/DC Activated PWR_ON = Negative going L → DC/DC switched Off, no power is applied to the associated output CRD_VCC pin. Since uncontrolled action could take place during the rise voltage of the related CRD_VCC_x output, care must be observed to avoid a PWR_ON negative going transient during this period of time. To avoid any logical latch up, using a minimum 1.0 ms delay is recommended prior to power down the related DC/DC converter following a power up command (Figure 12).
9	I/O_A	INPUT/OUTPUT	This pin carries the data transmission between an external microcontroller and the external smart card #A. A built-in bi-directional level translator adapts the signal flowing between the card and the MCU. The level translator is enabled when $\overline{CS}$ = Low. Since a dedicated line is used to communicate the data between the MPU and the smart card, the user can activate the two channels simultaneously, assuming the $\mu$ P provides a pair of I/O lines. When MUX_MODE = High, this pin provides an access to either card A or B I/O by means of CARD_SEL selection bit. On the other hand, the internal pull up resistor is automatically disconnected when MUX_MODE = High, avoiding a current overload on the I/O line, regardless of the EN_RPU logic level. This pull up resistor is under the EN_RPU control when MUX_MODE = Low.

# NCN6004A

## PIN DESCRIPTION (continued)

Pin	Symbol	Type	Description
10	RESET_A	INPUT	<p>The signal present on this pin is translated to the RST pin of the external smart card #A. The CS signal must be Low to validate the RESET function, regardless of the selected card. Assuming the <math>\mu</math>P provides two independent lines to control the RESET pins, the NCN6004A can control two cards simultaneously.</p> <p>When MUX_MODE = High, this pin provides an access to either card A or B Reset by means of CARD_SEL selection bit.</p> <p>The associated pull up resistor is either connected to <math>V_{CC}</math> (EN_RPU = H) or disconnected when EN_RPU = Low.</p>
11	C4_A	INPUT	<p>This pin controls the card #A C4 contact. The signal can be either de-multiplexed, at MPU level, or is multiplexed with C4_B, depending upon the MUX_MODE logic state.</p> <p>When MUX_MODE = High, this pin provides an access to either card A or B C4 channel by means of CARD_SEL selection bit.</p> <p>The associated pull up resistor is either connected to <math>V_{CC}</math> (EN_RPU = H) or disconnected when EN_RPU = Low.</p>
12	C8_A	INPUT	<p>This pin controls the card #A C8 contact. The signal can be either de-multiplexed, at MPU level, or is multiplexed with C8_B, depending upon the MUX_MODE logic state.</p> <p>When MUX_MODE = High, this pin provides an access to either card A or B C8 channel by means of CARD_SEL selection bit.</p> <p>The associated pull up resistor is either connected to <math>V_{CC}</math> (EN_RPU = H) or disconnected when EN_RPU = Low.</p>
13	CLOCK_IN_A	Clock Input, High Impedance	<p>The signal present on this pin comes from either the MCU master clock, or from any signal fulfilling the logic level and frequency specifications. This signal is fed to the internal clock selection circuit prior to be connected to the external smart card #A. Each of the external card can have different division ratio, depending upon the state of the CRD_SEL pin and associated programming bits. The built-in circuit can be programmed to 1/1, 1/2, 1/4 or 1/8 frequency division ratio.</p> <p>This input is valid and routed to either CRD_CLK_A_DIVIDER or CRD_CLK_B_DIVIDER regardless of the MUX_MODE state, depending upon the CLK_D_A/CRD_D_B and CARD_SEL programmed states (Table 1).</p> <p>Although this input supports the signal coming from a crystal oscillator, care must be observed to avoid digital levels outside the specified <math>V_{IH}/V_{IL}</math> range. Similarly, the input clock signal shall have rise and fall times compatible with the operating frequency.</p>
14	ANLG_GND	POWER	<p>This pin is the ground reference for both analog and digital signals and must be connected to the system Ground. Care must be observed to provide a copper PCB layout designed to avoid small signals and power transients sharing the same track. Good high frequency techniques are strongly recommended.</p>
15	CLOCK_IN_B	Clock Input, High Impedance	<p>The signal present on this pin comes from either the MCU master clock, or from any signal fulfilling the logic level and frequency specifications. This signal is fed to the internal clock selection circuit prior to be connected to the external smart card #B. Each of the external card can have different division ratio, depending upon the state of the CRD_SEL pin and associated programming bits. The built-in circuit can be programmed to 1/1, 1/2, 1/4, or 1/8 frequency division ratio.</p> <p>This input is valid and routed to either CRD_CLK_B_DIVIDER or CRD_CLK_A_DIVIDER regardless of the MUX_MODE state, depending upon the CRD_D_B/CRD_D_A and CARD_SEL programmed states (Table 1).</p> <p>Although this input supports the signal coming from a crystal oscillator, care must be observed to avoid digital levels outside the specified <math>V_{IH}/V_{IL}</math> range. Similarly, the input clock signal shall have rise and fall times compatible with the operating frequency.</p>
16	C8_B	INPUT	<p>This pin controls the card #B C8 contact. The signal can be either de-multiplexed, at MPU level, or is multiplexed with C8_A, depending upon the MUX_MODE logic state.</p> <p>When MUX_MODE = High, this pin is internally disable, a pull up resistor is connected to <math>V_{CC}</math> (regardless of the logic state of EN_RPU is), and the access to card B takes place by C8_A associated with CARD_SEL selection bit.</p> <p>The associated pull up resistor is either connected to <math>V_{CC}</math> (EN_RPU = H) or disconnected when EN_RPU = Low.</p>
17	C4_B	INPUT	<p>This pin controls the card #B C4 contact. The signal can be either de-multiplexed, at MPU level, or is multiplexed with C8_A, depending upon the MUX_MODE logic state.</p> <p>When MUX_MODE = High, this pin is internally disable, a pull up resistor is connected to <math>V_{CC}</math>, (regardless of the logic state of EN_RPU), and the access to card B takes place by C4_A associated with CARD_SEL selection bit.</p> <p>The associated pull up resistor is either connected to <math>V_{CC}</math> (EN_RPU = H) or disconnected when EN_RPU = Low.</p>

# NCN6004A

## PIN DESCRIPTION (continued)

Pin	Symbol	Type	Description
18	RESET_B	INPUT	<p>The signal present on this pin is translated to the RST pin of the external smart card #B. The <math>\overline{CS}</math> signal must be Low to valid the RESET function, regardless of the selected card. Assuming the <math>\mu</math>P provides two independent lines to control the RESET pins, and MUX_MODE = Low, the NCN6004A can control two cards simultaneously.</p> <p>When MUX_MODE = High, this pin is internally disable, a pull up resistor is connected to <math>V_{CC}</math>, (regardless of the logic state of EN_RPU), and the access to card B takes place by RESET_A associated with CARD_SEL selection bit.</p> <p>The associated pull up resistor is either connected to <math>V_{CC}</math> (EN_RPU = H) or disconnected when EN_RPU = Low.</p>
19	I/O_B	INPUT/OUTPUT	<p>This pin carries the data transmission between an external microcontroller and the external smart card #B.</p> <p>A built-in bi-directional level translator adapts the signal flowing between the card and the MCU. The level translator is enabled when <math>\overline{CS}</math> = Low. The signal present on this pin is latched when <math>\overline{CS}</math> = High. Since a dedicated line is used to communicate the data between the <math>\mu</math>P and the smart card, (assuming MUX_MODE = Low) the user can activate the two channels simultaneously, assuming the <math>\mu</math>P provides a pair of I/O lines. When MUX_MODE = High, this pin is internally disable, the pull up resistor is connected to <math>V_{CC}</math>, (regardless of the logic state of EN_RPU), and the access to card B takes place by I/O_A associated with CARD_SEL selection bit.</p>
20	CRD_DET_A	INPUT	<p>This pin senses the signal coming from the external smart card connector to detect the presence of card #A. The polarity of the signal is programmable as Normally Open or Normally Close switch. The logic signal will be activated when the level is either Low or High, with respect to the polarity defined previously. By default, the input is Normally Open. A built-in circuit prevents uncontrolled short pulses to generate an INT signal. The digital filter eliminates pulse width below 50<math>\mu</math>s (see spec).</p>
21	CRD_C8_A	OUTPUT	<p>This pin controls the card #A C8 contact, according to the ISO7816 specifications. A built-in level shifter is used to adapt the card and the <math>\mu</math>C, regardless of the power supply voltage of each signals.</p> <p>The signal present at this pin is latched upon either CARD_SEL = L, or <math>\overline{CS}</math> = H or PGM = L, and resume to a transparent mode when card #A is selected and operates in the transfer mode. The pin is hardwired to zero, the bias being provided by the <math>V_{CC}</math> supply, when either the <math>V_{CC}</math> voltage drops below 2.7 V, or during the CRD_VCC_A startup time.</p>
22	CRD_C4_A	OUTPUT	<p>This pin controls the card #A C4 contact, according to the ISO7816 specifications. A built-in level shifter is used to adapt the card and the MCU, regardless of the power supply voltage of each signals.</p> <p>The signal present at this pin is latched upon either CARD_SEL = L, or <math>\overline{CS}</math> = H, or PGM = L, and resume to a transparent mode when card #A is selected and operates in the transfer mode.</p> <p>The pin is hardwired to zero, the bias being provided by the <math>V_{CC}</math> supply, when either the <math>V_{CC}</math> voltage drops below 2.7 V, or during the CRD_VCC_A startup time.</p>
23	CRD_RST_A	OUTPUT	<p>This pin is connected to the external smart card #A to support the RESET signal. A built-in level shifter is used to adapt the card and the MCU, regardless of the power supply voltage of each signals.</p> <p>The signal present at this pin is latched upon either CARD_SEL = Low, or when <math>\overline{CS}</math> or PGM returns to a High, and resume to a transparent mode when card #A is selected. The pin is hardwired to zero, the bias being provided by the <math>V_{CC}</math> supply, when either the <math>V_{CC}</math> voltage drops below 2.7 V, or during the CRD_VCC_A startup time.</p>
24	CRD_IO_A	INPUT/OUTPUT	<p>This pin carries the data serial connection between the external smart card #A and the microcontroller. A built-in bidirectional level shifter is used to adapt the card and the MCU, regardless of the power supply voltage of each signals.</p> <p>This pin is biased by a pull up resistor connected to CRD_VCC_A. When <math>\overline{CS}</math> = High, the CRD_IO_A holds the previous I/O logic state and resume to a normal operation when this pin is reactivated.</p> <p>The pin is hardwired to zero, the bias being provided by the <math>V_{CC}</math> supply, when either the <math>V_{CC}</math> voltage drops below 2.7 V, or during the CRD_VCC_A start-up time.</p>
25	PWR_GND	POWER	<p>This pin carries the power current flow coming from the built in DC/DC converters. It is associated with the external card # A. It must be connected to the system Ground and care must be observed at PCB layout level to avoid the risk of spike voltages on the logic lines.</p>
26	L2_A	POWER	<p>Connects one side of the external DC/DC converter inductor #A (Note 1).</p>
27	L1_A	POWER	<p>Connects one side of the external DC/DC converter inductor #A (Note 1).</p>

1. The external inductors shall preferably have the same values. Depending upon the power absorbed by the load, the inductor can range from 10  $\mu$ H to 47  $\mu$ H. To achieve the highest yield, the inductor shall have an ESR < 1.0  $\Omega$ .

# NCN6004A

## PIN DESCRIPTION (continued)

Pin	Symbol	Type	Description
28	PWR_VCC_A	POWER	This pin is connected to the positive external power supply. The device sustains any voltage from +2.7 V to +5.5 V. This voltage supplies the NCN6004A internal circuits and is regulated by the internal DC/DC converter to provide the DC voltage to the external card. A high quality capacitor must be connected across pin 28 and PWR_GND, 10 $\mu$ F/6.0 V ceramic X7R or X5R type is recommended. Note: The voltage present at pin 28 and 33 must be equal to the voltage present at pin 42.
29	CRD_VCC_A	POWER	This pin provides the power supply to the external smart card #A. The $V_{CC}$ voltage is defined by programming the NCN6004A accordingly. Since the cards have independent DC/DC converter, the output voltage can have any value independently from CARD_B. A high quality, low ESR capacitor is mandatory to achieve the $V_{CC}$ specifications. Using two 4.7 $\mu$ F/6.0 V ceramic X7R or X5R capacitors in parallel is recommended.
30	CRD_CLK_A	OUTPUT	This pin is connected to the CLK external smart card #A pin. The signal comes from the built-in frequency divider dedicated to the #A card. The clock is selected and controlled by setting the logic inputs according to Table 1. The slope of the output clock can be selected between one of the two programmable mode: SLOW or FAST (Table 8). The pin is hardwired to zero, the bias being provided by the $V_{CC}$ supply, when either the $V_{CC}$ voltage drops below 2.7 V, or during the CRD_VCC_A startup time.
31	CRD_CLK_B	OUTPUT	This pin is connected to the CLK external smart card #B pin. The signal comes from the built-in frequency divider dedicated to the #B card. The clock is selected and controlled by setting the logic inputs according to Table 1. The slope of the output clock can be selected between one of the two programmable mode: SLOW or FAST (Table 8). The pin is hardwired to zero, the bias being provided by the $V_{CC}$ supply, when either the $V_{CC}$ voltage drops below 2.7 V, or during the CRD_VCC_B startup time.
32	CRD_VCC_B	POWER	This pin provides the power supply to the external smart card #B. The $V_{CC}$ voltage is defined by programming the NCN6004A accordingly. Since the cards have independent DC/DC converter, the output voltage can have any value independently from CARD_A. A high quality, low ESR capacitor is mandatory to achieve the $V_{CC}$ specifications. Using two 4.7 $\mu$ F/6.0 V ceramic X7R or X5R capacitors in parallel is recommended.
33	PWR_VCC_B	POWER	This pin is connected to the positive external power supply. The device sustains any voltage from +2.7 V to +6.0 V. This voltage supplies the NCN6004A internal circuits and is regulated by the internal DC/DC converter to provide the DC voltage to the external card. A high quality capacitor must be connected across pin 33 and PWR_GND, 10 $\mu$ F/6.0 V ceramic X7R type is recommended. Note: The voltage present on pin 28 and 33 must be equal to the voltage present on pin 42
34	L2b	POWER	Connects one side of the external DC/DC converter inductor #B (Note 1).
35	L1b	POWER	Connects one side of the external DC/DC converter inductor #B (Note 1).
36	PWR_GND	POWER	This pin carries the power current flow coming from the built in DC/DC converters. It is associated with the external card # B. It must be connected to the system Ground and care must be observed at PCB layout level to avoid the risk of spike voltages on the logic lines.
37	CRD_IO_B	INPUT/OUTPUT	This pin carries the data serial connection between the external smart card #B and the microcontroller. A built-in bi-directional level shifter is used to adapt the card and the MCU, regardless of the power supply voltage of each signals. This pin is biased by a pull up resistor connected to CRD_VCC_A. When $\overline{CS}$ = High, the CRD_IO_A holds the previous I/O logic state and resume to a normal operation when this pin is reactivated. The pin is hardwired to zero, the bias being provided by the $V_{CC}$ supply, when either the $V_{CC}$ voltage drops below 2.7 V, or during the CRD_VCC_B startup time.
38	CRD_RST_B	OUTPUT	This pin is connected to the external smart card #B to support the RESET signal. A built-in level shifter is used to adapt the card and the MCU, regardless of the power supply voltage of each signals. The signal present at this pin is latched upon either CARD_SEL or $\overline{CS}$ or $\overline{PGM}$ positive going transient and resume to a transparent mode when card #B is selected. The pin is hardwired to zero, the bias being provided by the $V_{CC}$ supply, when either the $V_{CC}$ voltage drops below 2.7 V, or during the CRD_VCC_B startup time.

1. The external inductors shall preferably have the same values. Depending upon the power absorbed by the load, the inductor can range from 10  $\mu$ H to 47  $\mu$ H. To achieve the highest yield, the inductor shall have an ESR < 1.0  $\Omega$ .

## NCN6004A

### PIN DESCRIPTION (continued)

Pin	Symbol	Type	Description
39	CRD_C4_B	OUTPUT	This pin controls the card #B C4 contact, according to the ISO specification. A built-in level shifter is used to adapt the card and the MCU, regardless of the power supply voltage of each signals. The signal present at this pin is latched upon either CARD_SEL or CS or PGM positive going transient and resume to a transparent mode when card #B is selected. The pin is hardwired to zero, the bias being provided by the V <sub>CC</sub> supply, when either the V <sub>CC</sub> voltage drops below 2.7 V, or during the CRD_VCC_B startup time.
40	CRD_C8_B	OUTPUT	This pin controls the card #B C8 contact, according to the ISO specification. A built-in level shifter is used to adapt the card and the MCU, regardless of the power supply voltage of each signals. The signal present at this pin is latched upon either CARD_SEL or CS or PGM positive going transient and resume to a transparent mode when card #B is selected. The pin is hardwired to zero, the bias being provided by the V <sub>CC</sub> supply, when either the V <sub>CC</sub> voltage drops below 2.7 V, or during the CRD_VCC_B startup time.
41	CRD_DET_B	INPUT	This pin senses the signal coming from the external smart card connector to detect the presence of card #B. The polarity of the signal is programmable as Normally Open or Normally Close switch. The logic signal will be activated when the level is either Low or High, with respect to the polarity defined previously. By default, the input is Normally Open. A built-in circuit prevents uncontrolled short pulses to generate an INT signal. The digital filter eliminates pulse width below 50 μs.
42	ANLG_VCC	POWER	This pin is connected to the positive external power supply. The device sustains any voltage from +2.7 V to +5.5 V. This voltage supplies the NCN6004A internal Analog and Logic circuits. A high quality capacitor must be connected across this pin and ANLG_GND, 10 μF/6 V is recommended. A set of extra pins (28 and 33) are provided to connect the power supply to the internal DC/DC converter. Note: The voltage present at pin 28 and 33 must be equal to the voltage present at pin 42
43	ANLG_GND	GROUND	This pin is the ground reference for both analog and digital signals and must be connected to the system Ground. Care must be observed to provide a copper PCB layout designed to avoid small signals and power transients sharing the same track. Good high frequency techniques are strongly recommended.
44	MUX_MODE	INPUT	This pin selects the mode of operation of the card signals from the MPU side. When MUX_MODE = Low, all the card signals are fully de-multiplexed and data transfers can take place with both cards simultaneously. On top of that, both cards can be accessed during the programming sequence, assuming the external microcontroller is capable to run multi tasks software. When MUX_MODE = High, all the card signals are multiplexed and the communications with the cards shall take place in a sequential mode. The card is selected by setting CARD_SEL high or Low. The internal logic will disable the CARD_B inputs and use CARD_SEL inputs as a single channel to controls both output smart cards sequentially when MUX_MODE = H. Moreover, when MUX_MODE = High, all the B channel μP dedicated pins, except CLOCK_IN_B, pin 15, are forced to a high level by means of internal pull up resistors. It is not necessary to connect these pins (16, 17, 18 and 19) to an external bias voltage, but it is mandatory to avoid any connections to ground. On the other hand, in this case the internal pull up resistor connected across I/O_A, pin 9 and V <sub>CC</sub> is automatically disconnected to avoid a current overload on the I/O line.
45	EN_RPU	INPUT	This pin provides a logic input to valid or not the internal pullup resistors connected across each I/O, RESET, C4 and C8 lines and ANLG_VCC. When EN_RPU = High, the pull up resistors are connected When EN_RPU = Low, the pull up resistors are disconnected and it is up to the designer to set up the external resistor to cope with the ISO/EMV specifications. The logic signal must be set up prior to apply the ANLG_VCC supply. Once the logic mode has been acknowledged by the internal Power On reset, it cannot be changed until a new startup sequence is launched.
46	STATUS	OUTPUT	This pin provides a logic state related to the card [A or B] insertion, the VCC_OK, the CRD_VCC value and the current overflow powered to either card [A or B]. The internal register can be read when PGM = High. The logic level is forced to High when the input voltage drops below the V <sub>bat</sub> min (2.0 V), thus reducing the stand by current, assuming the STATUS pin is not pulled down externally. The associated pullup resistor is either connected to V <sub>CC</sub> (EN_RPU = H) or disconnected when EN_RPU = Low.

# NCN6004A

## PIN DESCRIPTION (continued)

Pin	Symbol	Type	Description
47	INT	OUTPUT	This pin is activated LOW when a card has been inserted and detected in either of the external ports. The signal is reset by either a positive going transition on pin $\overline{CS}$ , or by a High level on pin PWR_ON combined with $\overline{CS} = \text{Low}$ . Similarly, an interrupt is generated when either one of the CRD_VCC output is overloaded. On the other hand, the pin is forced to a logic High when the input voltage $V_{CC}$ drops below 2.0 V min. The associated pull up resistor is either connected to $V_{CC}$ ( $EN\_RPU = H$ ) or disconnected when $EN\_RPU = \text{Low}$ .
48	ANLG_GND	GROUND	This pin is the ground reference for both analog and digital signals and must be connected to the system Ground. Care must be observed to provide a copper PCB layout designed to avoid small signals and power transients sharing the same track. Good high frequency techniques are strongly recommended.

## MAXIMUM RATINGS (Note 2)

Rating	Symbol	Value	Unit
Power Supply Input Supply Voltage	$V_{CC}$	6	V
$V_{in}$	Digital Input Pins	$-0.5 \text{ V} < V_{in} < V_{CC} + 0.5 \text{ V}$ , but $< 6.0 \text{ V}$	V
Power Supply Input Current	$I_{VCC}$	500	mA

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

2. Maximum Electrical Ratings are defined as those values beyond which damage(s) to the device may occur at  $T_A = +25^\circ\text{C}$ .

3. Human Body Model,  $R = 1500 \Omega$ ,  $C = 100 \text{ pF}$ .

4. Absolute Maximum Rating beyond which damage(s) to the device may occur.

## PROGRAMMING AND STATUS FUNCTIONS

The NCN6004A includes a programming interface and a status interface. Figure 4 illustrates the sequence one must follow to enter and exit the programming mode. Table 1 and Table 2 provide the logical functions associated with the

input and output signals. The parameters are latched upon the rising edge of the PGM signal, the  $\overline{CS}$  pin being held low. Any number of programming sequences can be performed while the  $\overline{CS}$  pin is Low, but the minimum timings must be observed.

**Figure 4. Programming Sequence**

On the other hand, since the programming data are latched upon the rising edge of the PGM signal, the most up to date selected card (using  $CARD\_SEL = H$  or  $L$ ) is used to activate the associated card. Consequently, when both cards must be updated with the same programmed content, a dual PGM sequence must be carried out, changing the  $CARD\_SEL$  signal during the High level state of the PGM pin.

Although selecting a card is possible during the same Chip Select sequence (as depicted here above), the user must

make sure that no data will be present to a card not ready for such a function. As a matter of fact, all the card signals are routed to the selected card immediately after a  $CARD\_SEL$  change, the NCN6004A taking no further logic control prior to activate the swap. To avoid any risk, one can run a sequence with the selected card, return  $\overline{CS}$  to High, change the  $CARD\_SEL$  according to the expected card selection, and pull  $\overline{CS}$  to Low to activate the selected card.

\*The STATUS register is not affected when the NCN6004A operates in any of the programming mode. Initialized conditions upon start-up are depicted by bold characters in Table 2 and Table 4.

The input power supply voltage monitoring applies to the card selected.

**Figure 5. Reading ANLG\_VCC Status (monitoring ANLG\_VCC input voltage)**

## SYSTEM STATES UPON UPON START-UP

**Table 4. Operating Conditions Upon Start-up**

CRD_VCC_A	3.0 V
CRD_VCC_B	3.0 V
CRD_CLK_A	1/1 Ratio
CRD_CLK_B	1/1 Ratio
CRD_CLK_A	START (clock is valid)
CRD_CLK_B	START (clock is valid)
CRD_CLK_A	Low Speed Slope
CRD_CLK_B	Low Speed Slope
CLOCK Route	Direct (CLK_A → A, CLK_B → B)

Depending upon the logic state at turn on present on pin 44, the system will run into a parallel mode (MUX\_MODE = L) or a multiplexed mode (MUX\_MODE = H). It is not possible to change the logic state once the system is running.

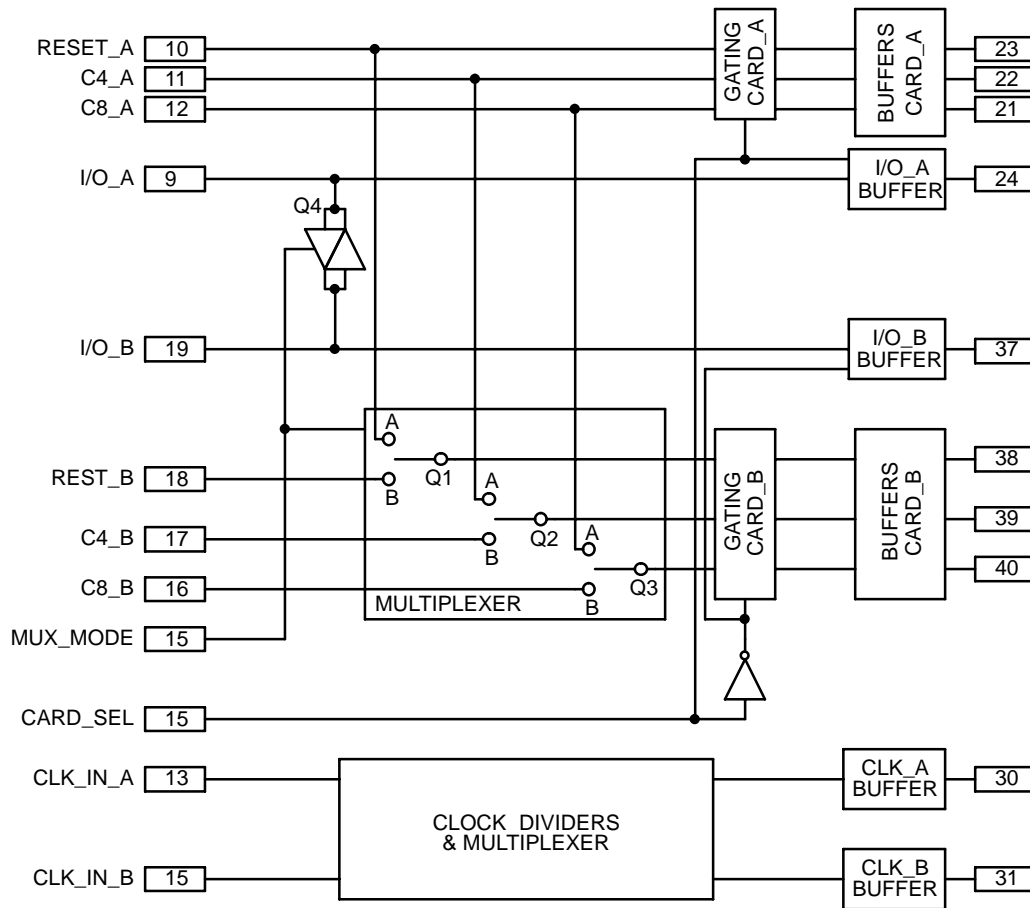

Similarly, depending upon the logic state present pin 45, the internal pull up resistors (I/O\_A and I/O\_B line) will be either connected to ANLG\_VCC voltage (EN\_RPU = H) or disconnected (EN\_RPU = L). It is not possible to change this operating condition once the system is running.

**PARALLEL/MULTIPLEXED OPERATION MODES**

The logic input MUX\_MODE, pin 44, provides a way to select the operation mode of the NCN6004A. Depending upon the logic level, the device operates either in a parallel mode (all the card pins, on the  $\mu$ P side, are fully independent)

or in multiplexed mode (all the logic card pins, on the  $\mu$ P side, share a common bus). Figure 6 shows a simplified schematic of the multiplex circuit built in the NCN6004A chip.

**Figure 6. Simplified MUX\_MODE Logic and Multiplex Circuit**

In both case, the device is programmed by means of the common logic controls pins (A0, A1, A2, A3, PGM, PWR\_ON, CARD\_SEL and  $\overline{CS}$ ). On the other hand, the logic status returned by the interface (STATUS pin 46) is shared by the two channels and can be read independently by setting CARD\_SEL accordingly.

The card related signals connected on the  $\mu$ C side are multiplexed or independent, depending upon the MUX\_MODE state as described here below.

**MUX\_MODE = Low → PARALLEL MODE**

When pin 44 is low, the device operates in the parallel mode. The transfer gate Q4 and the multiplexer circuit are disconnected and all the data will be carried out through their respective paths. The switches Q1, Q2 and Q3 are flipped to the B position, thus providing a direct connection from port B control signals to CARD\_B

All the CARD\_A and CARD\_B signals are independent and both cards can operate simultaneously, the data

transaction can take place at the same time and processed independently. Of course, the microcontroller must have the right data bus available to handle this process.

However, it is not possible to change the operating mode once the system has been started. If such a function is needed, one must pull down the related NCN6004A power supply, change the MUX\_MODE logic level, and re-start the interface.

**MUX\_MODE = High → MULTIPLEXED MODE**

When pin 44 is High, the device operates in a multiplexed mode and all the card signals are shared between CARD\_A and CARD\_B, except the input clocks which are independent at any time. The RST\_B, C4\_B and C8\_B pins are preferably left open at PCB level. The I/O\_B pin must be left open and cannot be connected to any external signal or bias voltages.

The transfer gate Q4 is switched ON, and, depending upon the CARD\_SEL logic level, the I/O data will be transferred

to either CARD\_A or CARD\_B. It is neither possible to connect directly I/O\_A to I/O\_B nor to connect the I/O\_B pin to ground or voltage supply.

The multiplexer is activated and the CARD\_SEL signal is used to select the card in use for a given transaction. The switches Q1, Q2 and Q3 are swapped to the A position, thus providing a path for the control signals applied to the CARD\_A side.

When the CARD\_SEL signal flips from one card to the other, the previous logic states of the on going card are latched in the chip and the related output card pin are maintained at the appropriate levels. When the system resumes to the previous card, the latches return to the transparent operation and the signals presented by the  $\mu$ P take priority over the previously latched states.

On the other hand, the input clocks (CLK\_IN\_A and CLK\_IN\_B) are maintained independent and can be routed to either CARD\_A or CARD\_B according to the programming functions given in Table 2.

**CARD POWER SUPPLY TIMING**

When the PWR\_ON signal is high, the associated CRD\_VCC\_A or CRD\_VCC\_B power supply rise time depends upon the current capability of the DC/DC converter together with the external inductors L1/L2 and the reservoir capacitor connected across each card power supply pin and GROUND.

On the other hand, at turn off, the CRD\_VCC\_A and CRD\_VCC\_B fall times depend upon the external reservoir capacitor and the peak current absorbed by the internal NMOS device built across each CRD\_VCC\_A/CRD\_VCC\_B and GROUND. These behaviors are depicted by Figure 7, assuming a 10  $\mu$ F output capacitor.

Since none of these parameters can have infinite values, the designer must take care of these limits if the  $t_{ON}$  or the  $t_{OFF}$  provided by the data sheets does not meet his requirement.

**Figure 7. Card Power Supply Turn ON and Shut OFF Typical Timings**

**POWER DOWN OPERATION**

The power down mode can be initiated by either the external MPU or by the internal error condition. The communication session is terminated immediately, according to the ISO7816-3 sequence. On the other hand, the MPU can run the Stand By mode by forcing CS = H, leaving the chip in the previous operating mode.

When the card is extracted, the interface will detect the operation and will automatically run the Power Down Sequence of the related card as described by the ISO/CEI 7816-3 sequence depicted in Figure 8 and illustrated by the oscillogram in Figure 9.

- Force RST to Low
- Force CLK to Low, unless it is already in this state
- Force C4 and C8 to Low
- Force CRD\_IO to Low
- Shut Off the CRD\_VCC Supply

**Figure 8. Card Power Down Sequence**

# NCN6004A

On the other hand, the Power Down sequence is automatically activated when the  $V_{bat}$  voltage drops below the VCC\_OK level, regardless of the logic conditions

present on the control pins, or when the related CRD\_VCC\_x output voltage reaches the overload condition.

Figure 9. Power Down Sequence

Figure 10. Power Down Sequence: Timing Details

**CARD DETECTION**

The card detector circuit provides a constant low current to bias the CRD\_DET\_A and CRD\_DET\_B pins, yielding a logic High when no card is present and the external switch is Normally Open type. The internal logic associated with pins 20 and 41 provides a programmable selection of the slope card detection. The transition is filtered out by the internal digital filter circuit, avoiding false interrupt. In addition to the typical 50 μs delay, the MPU shall provide an additional delay to cope with the mechanical stabilization of the card interface (typically 1 ms), prior to valid the CRD\_VCC\_A or CRD\_VCC\_B supply.

When a card is inserted, the detector circuit asserts  $\overline{INT}$  = Low as depicted before, the external μP being responsible to clear the interrupt signal, taking the necessary actions. When the NCN6004A detects a card extraction, the power down sequence is automatically activated for the related interface section, regardless of the PWR\_ON state, and the  $\overline{INT}$  pin is asserted Low. It is up to the external MPU to clear this interrupt by pulsing the  $\overline{CS}$  pin.

**Figure 11. Typical Interrupt Sequence**

The interrupt signal can be cleared either by a positive going slope on the Chip Select pin as depicted in Figure 11, or by forcing the PWR\_ON signal High (keeping  $\overline{CS}$  = Low) for the related card.

The polarity of the card detection switch can be either Normally Open or Normally Close and is software controlled as defined here below and in Table 2.

**Table 5. Card Detection Polarity**

CS	PGM	A3	A2	A1	A0	CARD_SEL	CRD_DET_A	CRD_DET_B
1	X	X	X	X	X	X	Qn -1	Qn -1
0	1	X	X	X	X	X	Qn -1	Qn -1
0	0	1	1	0	0	1	Normally Open	Qn -1
0	0	1	1	0	1	1	Normally Close	Qn -1
0	0	1	1	0	0	0	Qn -1	Normally Open
0	0	1	1	0	1	0	Bn -1	Normally Close

\*The polarity change is validated upon the next positive  $\overline{PGM}$  transient.

**POWER MANAGEMENT**

The main purpose of the power management is to provides the necessary output voltages to drive the 1.80 V, 3.0 V or 5.0 V smart card types. On top of that, the DC/DC converter efficiency must absorb a minimum current on the  $V_{bat}$  supply.

Beside the power conversion, in the Stand by mode ( $PWR\_ON = L$ ), the power management provides energy to the card detection circuit only. All the card interface pins are forced to ground potential, saving as much current as possible out of the battery supply.

In the event of a power up request coming from the external MPU ( $CARD\_SEL = H/L$ ,  $PWR\_ON = H$ ,  $\overline{CS} = L$ ), the power manager starts the DC/DC converter related to the selected interface section.

When the selected section (either  $CRD\_VCC\_A$  or  $CRD\_VCC\_B$ ) voltage reaches the programmed value (1.8 V, 3.0 V or 5.0 V), the circuit activates the card signals according to the following sequence:

$CRD\_VCC\_x \rightarrow CRD\_IO\_x \rightarrow CRD\_C4\_x \rightarrow CRD\_C8\_x \rightarrow CRD\_CLK\_x \rightarrow CRD\_RST\_x$

The logic level of the data lines are asserted High or Low, depending upon the state forced by the external MPU, when

the start-up sequence is completed. Under no situation the NCN6004A shall automatically launch a smart card ATR sequence.

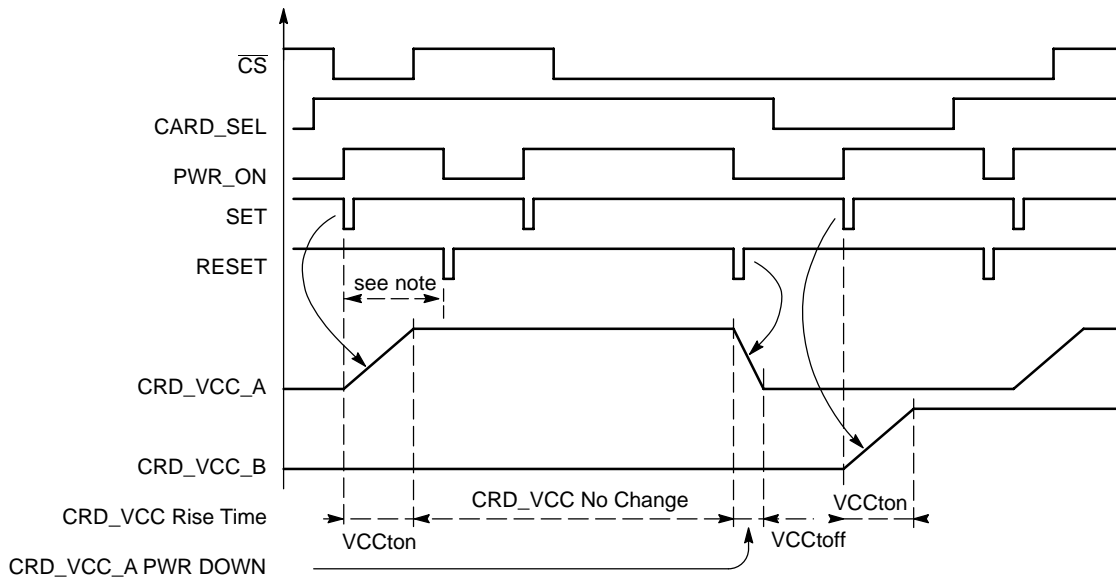

At the end of the transaction, asserted by the MPU ( $CARD\_SEL = H/L$ ,  $PWR\_ON = L$ ,  $\overline{CS} = L$ ), or under a card extraction, the ISO7816-3 power down sequence takes place:

$CRD\_RST\_x \rightarrow CRD\_CLK\_x \rightarrow CRD\_C4\_x \rightarrow CRD\_C8\_x \rightarrow CRD\_IO\_x \rightarrow CRD\_VCC\_x$

When  $\overline{CS} = H$ , the bi-directional I/O lines (pins 9 and 19) are forced into the High impedance mode to avoid signal collision with any data coming from the external MPU.

**OUTPUT VOLTAGE PROGRAMMING**

The internal logic provides a reliable circuit to activate any of the DC/DC converters safely. In particular, the Turn On/Turn Off of these converters is edge sensitive and controlled by the rising/falling edges of the  $PWR\_ON$  signal applied with Chip Select pin Low. The  $CARD\_SEL$  signal is used to select either  $CRD\_VCC\_A$  or  $CRD\_VCC\_B$  as defined by the functions programming in Table 2.

Note : minimum 1 ms delay before to send a power Off command to the same selected output is recommended.

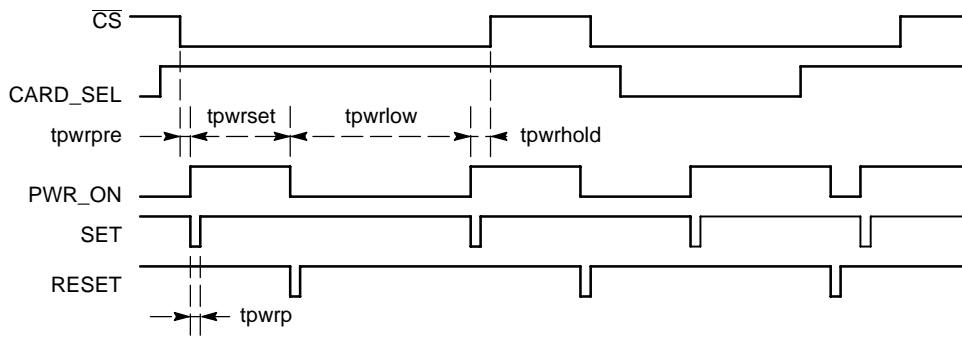

**Figure 12. Card Power Supply Controls**

Although it is possible to change the output voltage straightly from 5.0 V to 1.80 V, care must be observed as the stabilization time will be relatively long if no current is absorbed from the related output pin.

According to the typical sequence depicted, it is not possible to program simultaneously the two DC/DC

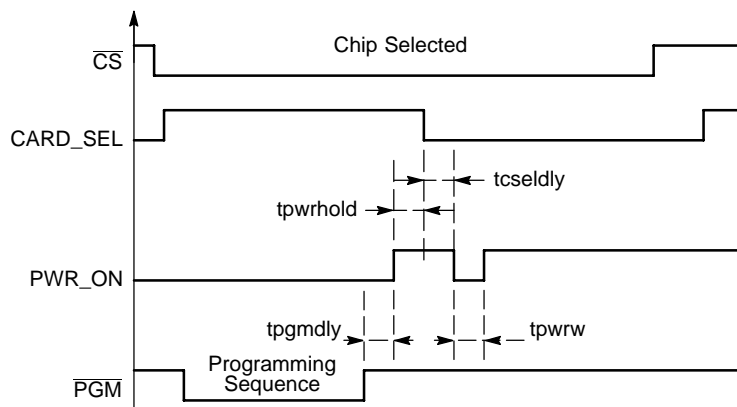

converters, but two separate sequences must take place. On top of that, since the circuit is edge sensitive, the  $PWR\_ON$  signal must present such a transient when a given state is expected for the converter. The  $PWR\_ON$  and  $\overline{CS}$  timings definitions are given in Figure 13.

## NCN6004A

NOTE: tpwrset: This delay is necessary to latch-up the PWR\_ON condition and does not represent the CRD\_VCC output voltage rise time.  
tpwrlow: This delay includes the internal ISO7816-3 power down sequence to make sure the DC/DC converter is fully deactivated.

**Figure 13. Power On Sequence Timings**

NOTE: tpwrw: This delay represents the minimum pulse width needed to write the PWR\_ON status into the associated DC/DC latch

**Figure 14. Power On and CARD\_SEL Sequence Timings**

### DC/DC CONVERTER

The power conversion is carried out either in step up or step down mode. The operation is fully automatic and, beside the output voltage programming, does not need any further adjustments.

The simplified DC/DC converter, given in Figure 15, is based on a full bridge structure capable to handle either step up or step down power supply using an external inductor. This structure brings the capability to operate from a wide range of input voltage, while providing the accurate 1.80 V, 3.0 V or 5.0 V requested by the smart cards. Beside the accuracy, the major aim of this structure is the high efficiency necessary to save energy taken from the battery. On the other hand, using two independent converters provides a high flexibility and prevent a total system crash in the event of a failure on one of the card connected to the interface.

### OPERATION

NOTE: Described operation makes reference to CARD\_A and can be applied to CARD\_B.

The system operates with a two cycles concept:

1. Cycle 1: Q15 and Q4 are switched ON and the inductor L1 is charged by the energy supplied by the external battery. During this phase, the pairs Q1/Q16 and Q2/Q3 are switched OFF. The current flowing into the two MOSFET Q1 and Q4 is internally monitored and will be switched OFF when the Ipeak value (depending upon the programmed output voltage value) is reached. At this point, Cycle 1 is completed and Cycle 2 takes place. The ON time is a function of the battery voltage and the value of the inductor network (L and Zr) connected across pins 26/27 and 34/35. A 4 μs time out structure makes sure the system does run in a continuous Cycle 1 loop.
2. Cycle 2: Q1 and Q16 are switched ON and the energy stored into the inductor L1 is dumped into the external load through Q16. During this phase, the pair Q15/Q4 and the pair Q2/Q3 are switched OFF. The current flow period is constant (900 ns typical) and Cycle 1 repeats after this time if the CRD\_VCC voltage is below the specified value.

# NCN6004A

When the output voltage reaches the specified value (1.80 V or 3.0 V or 5.0 V), Q1 and Q16 are switched OFF immediately to avoid over voltage on the output load. In the mean time, the two extra NMOS Q2 and Q3 are switched ON to fully discharge any current stored into the inductor, avoiding ringing and voltage spikes over the system. Figure 16 illustrates the theoretical basic waveforms present in the DC/DC converter.

The control block gives the logic states according to the bits provided by the external  $\mu\text{P}$ . These controls bits are applied to the selected DC/DC converter to generate the programmed output voltage. The MOS drive block includes the biases necessities to drive the NMOS and PMOS devices as depicted in the block diagram given Figure 15.

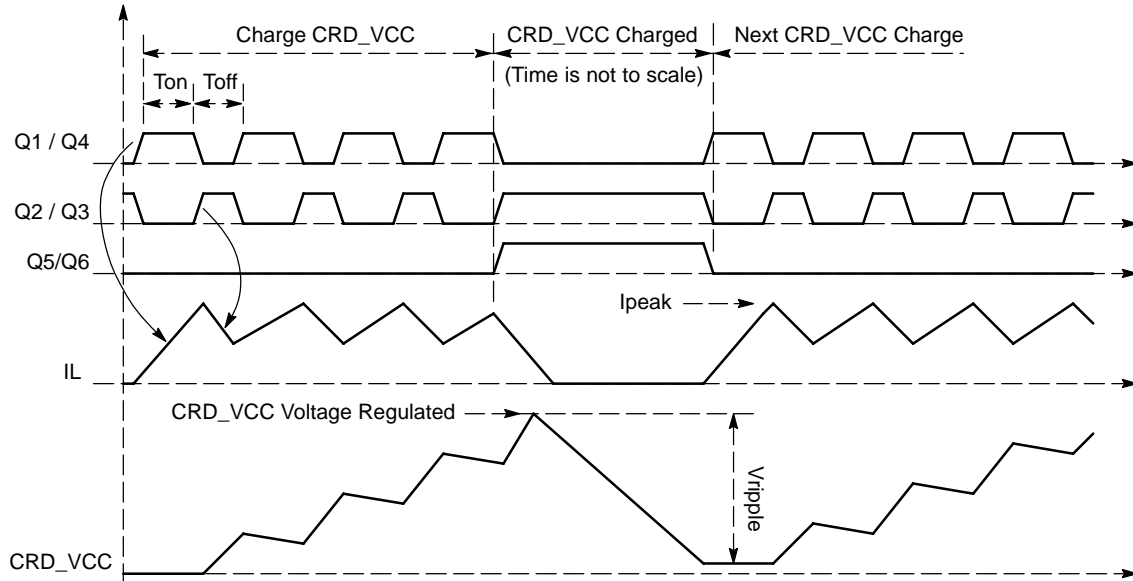

Figure 15. Basic DC/DC Converter Diagram

## NCN6004A

Since the output inductor L1 and the reservoir capacitor C1 carry relative high peak current, low ESR devices must be used to prevent the system from poor output voltage ripple and low efficiency. Using ceramic capacitors, X5R or X7R type, are recommended, splitting the 10  $\mu\text{F}$  in two separate parts when there is a relative long distance between

the CRD\_VCC\_x output pin and the card VCC input. On the other hand, the inductor shall have an ESR below 1.0  $\Omega$  to achieve the high efficiency over the full temperature range. However, inductor with 2.0  $\Omega$  ESR can be used when a slight decrease of the efficiency is acceptable at system level.

**Figure 16. Theoretical DC/DC Operating**

When the CRD\_VCC is programmed to zero volt, or when the card is extracted from the socket, the active pull down Q5 rapidly discharges the output reservoir capacitor, making sure the output voltage is below 0.40 V when the card slides across the contacts.

Based on the experiments carried out during the NCN6004A characterization, the best comprise, at time of printing this document, is to use two 4.7  $\mu\text{F}/10\text{ V}$ /ceramic/X7R capacitor in parallel to achieve the CRD\_VCC filtering. The ESR will not extend 50 m $\Omega$

over the temperature range and the combination of standard parts provide an acceptable  $-20\%$  to  $+20\%$  tolerance, together with a low cost. Table 6 shows a quick comparison between the most common type of capacitors. Obviously, the capacitor must be SMD type to achieve the extremely low ESR and ESL necessary for this application.

Figure 17 illustrates the CRD\_VCC ripple observed in the NCN6004A demo board running with X7R ceramic capacitors.

**Table 6. Ceramic/Electrolytic Capacitors Comparison**

Manufacturer	Type/Series	Format	Max Value	Tolerance	Typ. Z @ 500 kHz
MURATA	CERAMIC/GRM225	0805	10 $\mu\text{F}/6.3\text{ V}$	$-20\%$ / $+20\%$	30 m $\Omega$
MURATA	CERAMIC/GRM225	0805	4.7 $\mu\text{F}/6.3\text{ V}$	$-20\%$ / $+20\%$	30 m $\Omega$

VISHAY	Electrolytic/94SV	1812	10 $\mu\text{F}/10\text{ V}$	$-20\%$ / $+20\%$	400 m $\Omega$
Miscellaneous	Electrolytic Low Cost	1812	10 $\mu\text{F}/10\text{ V}$	$-35\%$ / $+50\%$	2.0 $\Omega$

NOTE: Operating conditions under full output load.

Figure 17. Typical CRD\_VCC Ripple Voltage

Figure 18. Typical Card Voltage Turn ON and Start-up Sequence

Figure 19. Typical Card Supply Turn OFF

Figure 20. CRD\_VCC Efficiency as a Function of the Input Supply Voltage

The curves in Figure 20, illustrate the typical behavior under full output current load (35 mA, 60 mA and 65 mA), according to EMV specifications.

During the operation, the inductor is subject to high peak current as depicted in Figure 21 and the magnetic core must sustain this level of current without damage. In particular, the ferrite material shall not be saturated to avoid uncontrolled current spike during the charge up cycle. Moreover, since the DC/DC efficiency depends upon the losses developed into the active and passive components, selecting a low ESR inductor is preferred to reduce these losses to a minimum.

# NCN6004A

**Figure 21. Typical Output Voltage Ripple**

According to the ISO7816-3 and EMV specifications, the interface shall limit the CRD\_VCC output current to 200 mA maximum, under short circuit conditions. The

NCN6004A supports such a parameter, the limit being depending upon the input and output voltages as depicted in Figure 22.

**Figure 22. Output Current Limit**

Beside the continuous current capability, the smart card power supply must be capable of providing a 100 mA pulsed current during the data transaction. The ISO7816-3, paragraph 4.3.2, defines this 400 ns pulse as a function of the

**Figure 23. Output Current Limit as a Function of the Temperature**

environment. As a matter of fact, this pulse does not come solely from the NCN6004A DC/DC converter, but the reservoir capacitor and the associated PCB tracks shall be considered as well.

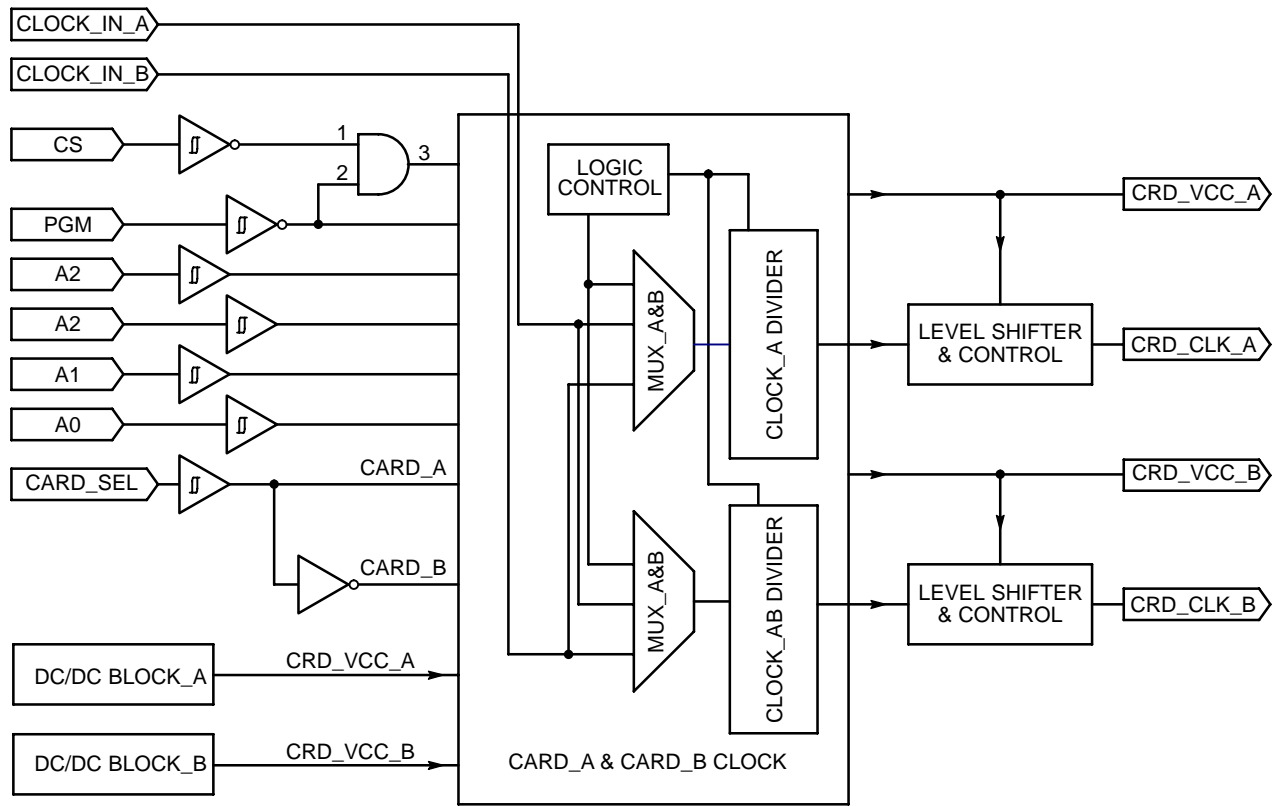

**CLOCK DIVIDER**

The main purpose of the built in clock generator is four folds:

1. Adapts the voltage level shifter to cope with the different voltages that might exist between the MPU and the Smart Card
2. Provides a frequency division to adapt the Smart Card operating frequency from the external clock source.
3. Control the clock state according to the smart card specification.
4. Provides an input clock re-routing to route the CLOCK\_IN\_A and CLOCK\_IN\_B signals to either CRD\_CLK\_A or CRD\_CLK\_B output pins.

In addition, the NCN6004A adjusts the signal coming from the microprocessor to get the Duty Cycle window as defined by the ISO7816-3 specification.

The logic input pins  $\overline{\text{CARD\_SEL}}$ , A0, A1,  $\overline{\text{PGM}}$ , I/O and  $\overline{\text{RESET}}$  fulfill the programming functions when both  $\overline{\text{PGM}}$  and  $\overline{\text{CS}}$  are Low. The clock input stage (CLOCK\_IN) can handle a 40 MHz frequency maximum, the divider being capable to provide an 1:8 ratio. Of course, the ratio must be defined by the engineer to cope with the Smart Card considered in a given application and, in any case, the output clock (CRD\_CLK\_A and CRD\_CLK\_B) shall be limited to 20 MHz maximum when the system is considered to operate over the full temperature range.

**Figure 24. Simplified Frequency Divider and Programming Functions**

In order to avoid any duty cycle out of the frequency smart card ISO7816-3 and EMV specifications, the clock divider is synchronized by the last flip flop, thus yielding a constant 50% duty cycle, regardless of the divider ratio.

Consequently, the output CRD\_CLK\_A or CRD\_CLK\_B frequency division can be delayed by eight CLOCK\_IN pulses and the microcontroller software must take this delay into account prior to launch a new data transaction.

# NCN6004A

**Figure 25. Clock Programming Timings**

The example given in Figure 25 highlights the delay coming from the internal clock duty cycle re-synchronization. Since the clock signal is asynchronous, it is up to the programmer to make sure the next card transaction is not activated before, respectively, either the

CRD\_CLK\_A or CRD\_CLK\_B signal has been updated. Generally speaking, such a delay can be derived from the maximum clock frequency provided to the interface.

**Figure 26. Card Clock 1/2 Divider Operation**

# NCN6004A

Figure 27. Clock Divider: 8 to 1 Operation

Figure 28. Clock Divider Timing Details

Figure 29. Clock Divider: Run to Stop High Operation

# NCN6004A

The input clock A and B can be re routed to either CRD\_CLK\_A or CRD\_CLK\_B output pins by using the programming function as defined in Table 2 and Table 7. The clock signals can have any frequency value necessary to handle a given type of card (asynchronous or synchronous).

These clock signals can be multiplexed at any time, but the system must be locked in a safe state prior to make such a change. In particular, the designer must make sure that A and B cards can support such a hot change prior to change the related clocks.

**Table 7. Programming Clock Routing**

STATE	CS	PGM	A3	A2	A1	A0	CARD_SEL	CRD_CLK_A	CRD_CLK_B	
0E	0	0	1	1	1	0	1	CLK_D_A	-	Default
0F	0	0	1	1	1	1	1	CLK_D_B	-	-
0E	0	0	1	1	1	0	0	-	CLK_D_B	Default
0F	0	0	1	1	1	1	0	-	CLK_D_A	-

On the other hand, the slope of the CRD\_CLK\_x signal can be set to either FAST or SLOW, depending upon the

frequency of the output clock. This selection is achieved by programming the chip according to Table 8.

**Table 8. Output Clock Slope Selection**

STATE	CS	PGM	A3	A2	A1	A0	CARD_SEL	CLOCK SLOPE	
\$03	0	0	0	0	1	1	1	SLOW	Default
\$0B	0	0	1	0	1	1	1	FAST	-
\$03	0	0	0	0	1	1	0	SLOW	Default
\$0B	0	0	1	0	1	1	0	FAST	-

**Figure 30. Typical Rise and Fall Time in Fast and Slow Operating Mode**

## PARALLEL OPERATION

When two or more NCN6004A parts operate in parallel on a common digital bus, the Chip Select pin allows the selection of one chip from the bank of the paralleled devices. Of course, the external MPU shall provide one unique CS line for each of the NCN6004A considered interface. When a given interface is selected by CS = L, all the logic inputs becomes active, the chip can be programmed or/and the external card can be accessed. When CS = H, all the input logic pins are in the high impedance state, thus leaving the bus available for other purpose.

The pull up resistors connected on each logic input lines on the MPU side (see block diagram in Figure 30), can be either activated (connected to V<sub>CC</sub>) or disconnected, depending upon the logic state present at EN\_RPU, pin 45. When these resistors are disconnected, it is the system responsibility to set up the external pull up resistors according to the application's requirements.

When the device operates in the multiplexed mode (MUX\_MODE = High), the internal card #B pull up resistors are connected to V<sub>CC</sub>, regardless of the EN\_RPU logic state.

On the other hand, when  $\overline{CS} = H$ , the CRD\_IO and CRD\_RST hold the previous I/O and RESET logic state, the CRD\_CLK being either active or stopped and the CRD\_VCC output voltage will maintain is previous value, according to the programmed state forced by the MPU.

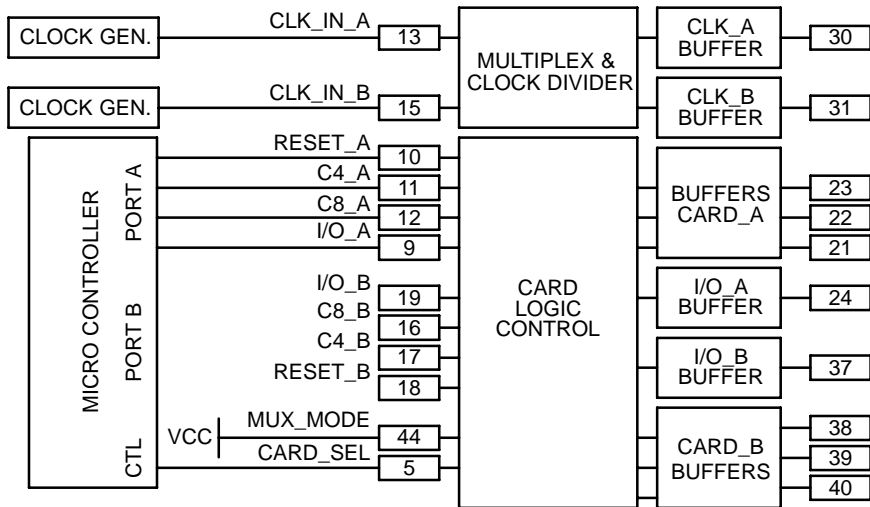

# NCN6004A

**Figure 31. Parallel Operation Wiring → MUX\_MODE = Low**

When the chip operates in the parallel mode, all the logic signals must be independently controlled by the microcontroller as depicted in Figure 31. The MUX\_MODE pin must be hardwired to VCC and it cannot be changed

during an operation of the chip. Beside this parameter, the user must select to force or not the internal pull up resistors as defined by the EN\_RPU logic state.

**Figure 32. Multiplexed Operation Wiring → MUX\_MODE = High**

In the multiplexed mode, the microprocessor CARD\_B side pins are not connected, the logic signals and the I/O line being shared with CARD\_A associated with the CRD\_SEL control bit: Figure 32. A key point is to make sure there is no connection associated with the I/O\_B pin since this pin is internally shared with the I/O line transaction. The CLK\_IN\_A and CLK\_IN\_B signals are independent and can be routed to any of the card thanks to the built-in clock multiplexer.

### DATA I/O LEVEL SHIFTER

The built in structure provides a level shifter on each card output signals, the I/O line being driven differently as depicted in Figure 33. Since the NCN6004A can operate in

either a multiplexed or parallel mode, provisions have been made to route the I/O\_A input pin to either CARD\_A or CARD\_B.

In both case, the I/O pins are driven by an open drain structure with a 20 kΩ pull up resistor as shown Figure 33. To achieve the 0.80 μs maximum rise time requested by the EMV specifications, an accelerator circuit is added on both side of each I/O line. These pulsed circuits yield boost current to charge the stray capacitance, thus accelerating the positive going slope of the I/O signal. On the other hand, the active pull down NMOS device Q5 provides a low impedance to ground during the battery up and DC/DC start-up phase, avoiding any uncontrolled voltage spikes on the I/O lines.

# NCN6004A

## MUX\_MODE = Low → PARALLEL OPERATION

The bi-directional switch Q9 is OFF and the I/O signals are routed straightforward to their appropriate outputs. The two I/O lines can operate simultaneously, depending upon the  $\mu$ P capabilities, regardless of the CARD\_SEL signal logic level.

The pull up resistors, on the  $\mu$ P side of each I/O line, can be connected or not as defined by the EN\_RPU signal.

## MUX\_MODE = High → MULTIPLEXED OPERATION

The bi-directional switch Q9 is ON and the I/O\_A pin is used to handle data for CARD\_A and CARD\_B. The signal

is routed to the appropriate card by means of the CARD\_SEL logic signal. In this mode, the I/O\_B pin 19 must be left open since the internal data signal will be present on this pin.

Moreover, since R1 and R3 are in parallel, the pull up resistor R1 is automatically disconnected to maintain the I/O line impedance to 20 k $\Omega$  (typical), what ever be the EN\_RPU logic level. This feature makes sure the current flowing trough the external card is limited to 500  $\mu$ A during a low level state.

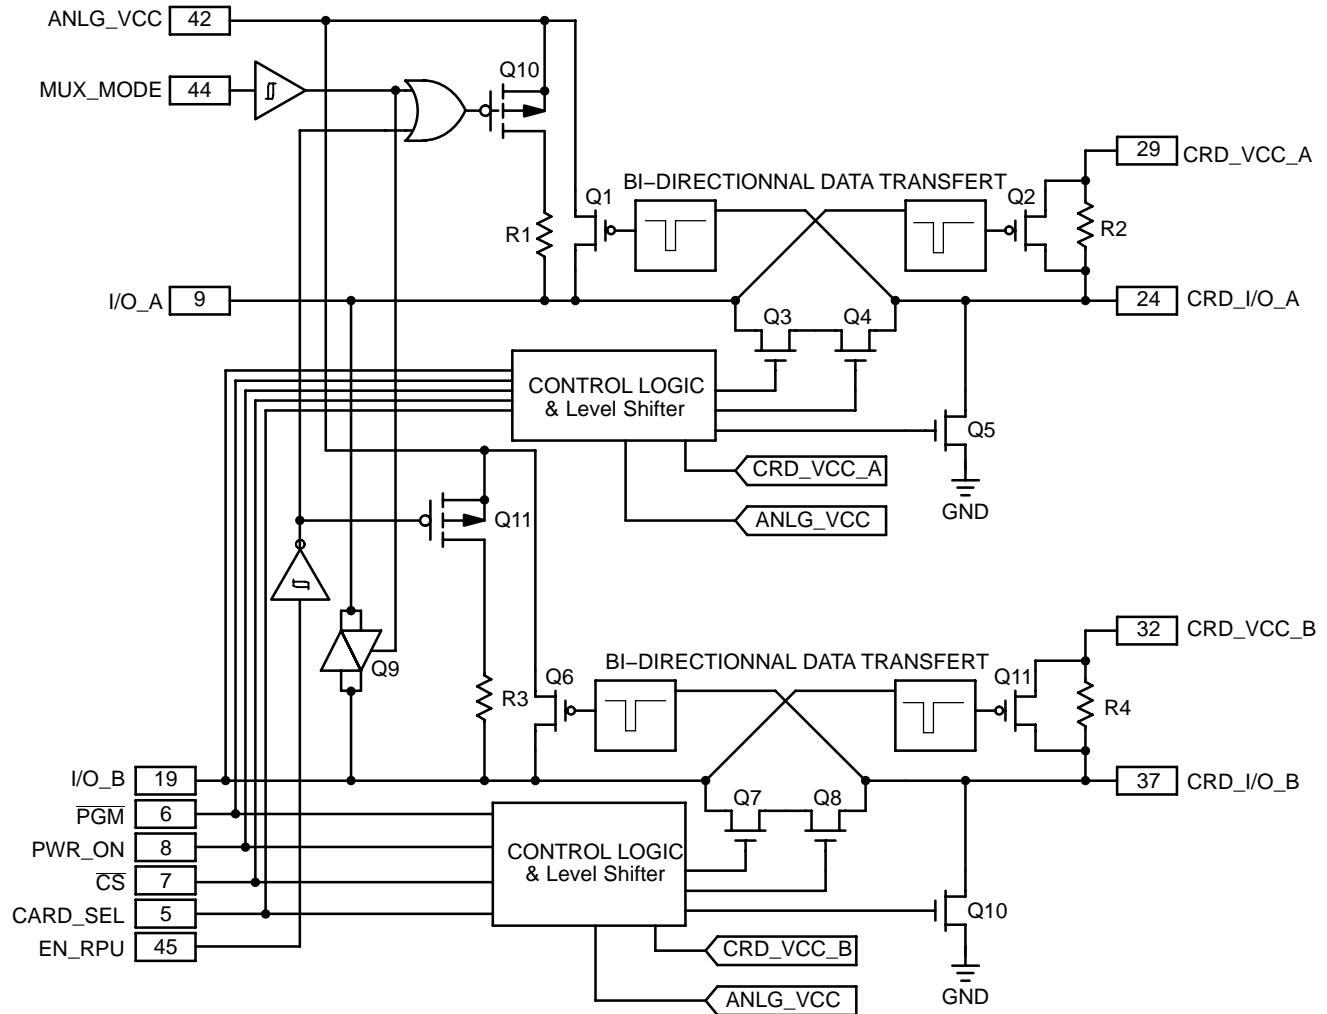

Figure 33. Dual Bi-directional I/O Line Level Shifter and Multiplex

Figure 34. Typical I/O Rise and Fall Time

### ESD Protection

The NCN6004A includes silicon devices to protect the pins against the ESD spikes voltages. To cope with the different ESD voltages developed across these pins, the built in structures have been designed to handle either 2 kV, when related to the microcontroller side, or 8 kV when connected with the external contacts. Practically, the CRD\_RST, CRD\_CLK, CRD\_IO, CRD\_C4 and CRD\_C8 (both A and B sections) pins can sustain 8 kV, the maximum short circuit current being limited to 15 mA. The CRD\_VCC\_A and CRD\_VCC\_B pins have the same ESD protection, but can source up to 65 mA continuously each, the absolute maximum current being 150 mA per section.

### Security Features

In order to protect both the interface and the external smart card, the NCN6004A provides security features to prevent catastrophic failures as depicted here after.

**Pin Current Limitation:** in case of a short circuit to ground, the current forced by the device is limited to 10 mA for any pins, except CRD\_CLK\_A and CRD\_CLK\_B pins

which are both limited to 70 mA. No feedback is provided to the external MPU.

**DC/DC Operation:** The internal circuit continuously senses the CRD\_VCC\_A and CRD\_VCC\_B voltages and, in the case of either over or under voltage situation, update the STATUS register accordingly. This register can be read out by the MPU but no interrupts are activated.

**DC/DC Overload:** When an overload is sensed across the CRD\_VCC\_A or CRD\_VCC\_B output, during either the power on sequence or when the system was previously running, the NCN6004A generates an interrupt by pulling down the  $\overline{\text{INT}}$  pin. It is up to the microcontroller to identify the origin of the overload by reading the STATUS pin accordingly.

**Battery Voltage:** Both the Positive going and the Negative going voltage are detected by the NCN6004A, a POWER\_DOWN sequence and the STATUS register being updated accordingly. The external MPU can read the STATUS pin to take whatever is appropriate to cope with the situation. The NCN6004A does not provide any further internal voltage regulation.
