## LIN Transceiver with Voltage Regulator and Reset Pin

ON Semiconductor®

[www.onsemi.com](http://www.onsemi.com)

### General Description

The NCV7425 is a fully featured local interconnect network (LIN) transceiver designed to interface between a LIN protocol controller and the physical bus.

The NCV7425 LIN device is a member of the in-vehicle networking (IVN) transceiver family of ON Semiconductor that integrates a LIN v2.1 physical transceiver and a low-drop voltage regulator.

The LIN bus is designed to communicate low rate data from control devices such as door locks, mirrors, car seats, and sunroofs at the lowest possible cost. The bus is designed to eliminate as much wiring as possible and is implemented using a single wire in each node. Each node has a slave MCU-state machine that recognizes and translates the instructions specific to that function. The main attraction of the LIN bus is that all the functions are not time critical and usually relate to passenger comfort.

### Features

- LIN-Bus Transceiver
  - ◆ LIN compliant to specification revision 2.1 (backward compatible to versions 2.0 and 1.3) and J2602
  - ◆ Bus Voltage  $\pm 45$  V
  - ◆ Transmission Rate up to 20 kBaud
  - ◆ Integrated Slope Control for Improved EMI Compatibility
- Package
  - ◆ SOIC-16 Wide Body Package with Exposed Pad
- Protection
  - ◆ Thermal Shutdown
  - ◆ Indefinite Short-Circuit Protection on Pins LIN and WAKE Towards Supply and Ground
  - ◆ Load Dump Protection (45 V)
  - ◆ Bus Pins Protected Against Transients in an Automotive Environment
  - ◆ ESD Protection Level for LIN, INH, WAKE and  $V_{BB}$  up to  $\pm 10$  kV
- Voltage Regulator
  - ◆ Two Device Versions: Output Voltage 3.3 V or 5 V For Loads up to 150 mA
  - ◆ Undervoltage Detector with a Reset Output to the Supplied Microcontroller
  - ◆ INH Output for Auxiliary Purposes (switching of an external pull-up or resistive divider towards battery, control of an external voltage regulator etc.)

### ORDERING INFORMATION

See detailed ordering and shipping information in the package dimensions section on page 19 of this data sheet.

- Modes
  - ◆ Normal Mode: LIN Communication in Either Low (up to 10 kBaud) or Normal Slope
  - ◆ Sleep Mode:  $V_{CC}$  is Switched “off” and No Communication on LIN Bus
  - ◆ Standby Mode:  $V_{CC}$  is Switched “on” but There is No Communication on LIN Bus
  - ◆ Wake-up Bringing the Component From Sleep Mode Into Standby Mode is Possible Either by LIN Command or Digital Input Signal on WAKE Pin Wake-up from LIN Bus can also be Detected and Flagged When the Chip is Already in Standby Mode

### Quality

- NCV Prefix for Automotive and Other Applications Requiring Unique Site and Control Change Requirements; AEC-Q100 Qualified and PPAP Capable
- These Devices are Pb-Free, Halogen Free/BFR Free and are RoHS Compliant

### Typical Applications

- Automotive
- Industrial Networks

## TYPICAL APPLICATION

### Application Information

The EMC immunity of the Master-mode device can be further enhanced by adding a capacitor between the LIN output and ground. The optimum value of this capacitor is determined by the length and capacitance of the LIN bus, the number and capacitance of Slave devices, the pull-up resistance of all devices (Master and Slave), and the required time constant of the system, respectively.

V<sub>CC</sub> voltage must be properly stabilized by external capacitors: capacitor of min. 80 nF (ESR < 10 mΩ) in parallel with a capacitor of min. 8 μF (ESR < 1 Ω).

The 10 μF capacitor on the battery is optional and serves as reservoir capacitor to deal with battery supply micro-cuts.

## FUNCTIONAL DESCRIPTION

### Overall Functional Description

LIN is a serial communication protocol that efficiently supports the control of mechatronic nodes in distributed automotive applications. The domain is class-A multiplex buses with a single master node and a set of slave nodes.

NCV7425 is designed as a master or slave node for the LIN communication interface with an integrated 3.3 V or 5 V voltage regulator having a current capability up to 150 mA for supplying any external components (microcontroller, CAN node, etc.).

NCV7425 contains the LIN transmitter, LIN receiver, voltage regulator, power-on-reset (POR) circuits and thermal shutdown (TSD). The LIN transmitter is optimized for the maximum specified transmission speed of 20 kBaud

with EMC performance due to reduced slew rate of the LIN output.

The junction temperature is monitored via a thermal shutdown circuit that switches the LIN transmitter and voltage regulator off when temperature exceeds the TSD trigger level.

NCV7425 has four operating states (normal mode, low slope mode, standby mode, and sleep mode) that are determined by the input signals EN, WAKE, STB, and TxD.

### Operating States

NCV7425 provides four operating states, two modes for normal operation with communication, one standby without communication and one low power mode with very low current consumption – see Figure 4 and Table 4.

Table 4. MODE SELECTION

Mode	V <sub>CC</sub>	RxD	INH	LIN Transceiver	30 kΩ on LIN	RSTN
Normal – Slope (Note 3)	ON	Low = Dominant State High = Recessive State	High if STB = High during state transition; Floating otherwise	Normal Slope	ON	High
Normal – Low Slope (Note 4)	ON	Low = Dominant State High = Recessive State	High if STB = High during state transition; Floating otherwise	Low Slope	ON	High
Standby (Note 5)	ON	Low after LIN wake-up, High otherwise (Note 6)	Floating	OFF	OFF	Controlled by V <sub>CC</sub> undervoltage monitor
Sleep	OFF	Clamped to V <sub>CC</sub> (Note 6)	Floating	OFF	OFF	Low

3. The normal slope mode is entered when pin EN goes High while TxD is in High state during EN transition.
4. The low slope mode is entered when pin EN goes High while TxD is in Low state during EN transition. LIN transmitter gets on only after TxD returns to High after the state transition.
5. The standby mode is entered automatically after power-up.
6. In standby and Sleep mode, the High state is achieved by internal pull-up resistor to V<sub>CC</sub>.

Figure 4. State Diagram

PD20090610.01

**Normal Slope Mode**

In normal slope mode the transceiver can transmit and receive data via LIN bus with speed up to 20 kBaud. The transmit data stream of the LIN protocol is present on the TxD pin and converted by the transmitter into a LIN bus signal with controlled slew rate to minimize EMC emission. The receiver consists of the comparator that has a threshold with hysteresis in respect to the supply voltage and an input filter to remove bus noise. The LIN output is pulled High via an internal 30 kΩ pull-up resistor. For master applications it is needed to put an external 1 kΩ resistor with a serial diode between LIN and V<sub>BB</sub> (or INH) – see Figure 2. The

mode selection is done by EN=High when TxD pin is High. If STB pin is High during the standby-to-normal slope mode transition, INH pin is pulled High. Otherwise, it stays floating.

**Low Slope Mode**

In low slope mode the slew rate of the signal on the LIN bus is reduced (rising and falling edges of the LIN bus signal are longer). This further reduces the EMC emission. As a consequence the maximum speed on the LIN bus is reduced up to 10 kBaud. This mode is suited for applications where the communication speed is not critical. The mode selection

is done by EN=High when TxD pin is Low. In order not to transmit immediately a dominant state on the bus (because TxD = Low), the LIN transmitter is enabled only after TxD returns to High. If STB pin is High during the standby-to-low slope mode transition, INH pin is pulled High. Otherwise, it stays floating.

**Standby Mode**

The standby mode is always entered after power-up of the NCV7425. It can also be entered from normal mode when the EN pin is Low and the standby pin is High. From sleep mode it can be entered after a local wake-up or LIN wake-up. In standby mode the V<sub>CC</sub> voltage regulator for supplying external components (e.g. a microcontroller) stays active. Also the LIN receiver stays active to be able to detect a remote wake-up via bus. The LIN transmitter is disabled and the slave internal termination resistor of 30 kΩ between LIN and V<sub>BB</sub> is disconnected in order to minimize current consumption. Only a pull-up current source between V<sub>BB</sub> and LIN is active.

**Sleep Mode**

The Sleep Mode provides extremely low current consumption. This mode is entered when both EN and STB pins are Low coming from normal mode. The internal termination resistor of 30 kΩ between LIN and V<sub>BB</sub> is disconnected and also the V<sub>CC</sub> regulator is switched off to minimize current consumption.

**Wake-up**

NCV7425 has two possibilities to wake-up from sleep or standby mode (see Figure 4):

Local wake-up: enables the transition from sleep mode to standby mode

Remote wake-up via LIN: enables the transition from sleep to standby mode and can be also detected when already in standby mode.

A local wake-up is **only** detected in sleep mode if a transition from Low to High or from High to Low is seen on the WAKE pin.

Figure 5. Local Wake-Up Signal

PC20060427.3

A remote wake-up is **only** detected if a combination of (1) a falling edge at the LIN pin (transition from recessive to dominant) is followed by (2) a dominant level maintained

for a time period > t<sub>WAKE</sub> and (3) again a rising edge at pin LIN (transition from dominant to recessive) happens.

Figure 6. Remote Wake-Up Behavior

PC20060427.2

The wake-up source is distinguished by pin RxD in the standby mode:

RxD remains High after power-up or local wake-up.

RxD is kept Low until normal mode is entered after a remote wake-up (LIN)

**V<sub>CC</sub> Undervoltage Detection and RSTN Pin**

In standby, normal and low slope modes, the V<sub>CC</sub> regulator is monitored. Whenever the regulator output falls below V<sub>CC\_UV\_THR</sub> level (typically 90% of the nominal voltage) for longer than V<sub>CC\_UV\_deb</sub> (typically 5 μs), an

# NCV7425

undervoltage is detected. Output pin RSTN is pulled to Low level to indicate the undervoltage condition to the external load (a microcontroller). At the same time, the device enters automatically the standby mode. As soon as the regulator output returns above the undervoltage level, the RSTN Low level is extended by typically 6ms and only then released to High level in order to ensure microcontroller initialization under correct supply conditions.

In the sleep mode, RSTN pin is kept Low regardless the  $V_{CC}$  level – it means that RSTN becomes Low immediately at sleep mode entry even if the  $V_{CC}$  capacitor is still charged.

In all situations where RSTN pin is kept Low, the digital inputs to NCV7425 are discarded by the internal control logic and have no effect on its behavior.

The RSTN pin function is illustrated in Figure 7.
