NCV7420

LIN Transceiver with 3.3 V or 5 V Voltage Regulator

General Description

The NCV7420 is a fully featured local interconnect network (LIN) transceiver designed to interface between a LIN protocol controller and the physical bus. The transceiver is implemented in I3T technology enabling both high-voltage analog circuitry and digital functionality to co-exist on the same chip.

The NCV7420 LIN device is a member of the in-vehicle networking (IVN) transceiver family of ON Semiconductor that integrates a LIN v2.0/2.1 physical transceiver and either a 3.3 V or a 5 V voltage regulator.

The LIN bus is designed to communicate low rate data from control devices such as door locks, mirrors, car seats, and sunroofs at the lowest possible cost. The bus is designed to eliminate as much wiring as possible and is implemented using a single wire in each node. Each node has a slave MCU-state machine that recognizes and translates the instructions specific to that function. The main attraction of the LIN bus is that all the functions are not time critical and usually relate to passenger comfort.

Typical Application

Application Schematic

The EMC immunity of the Master-mode device can be further enhanced by adding a capacitor between the LIN output and ground. The optimum value of this capacitor is

determined by the length and capacitance of the LIN bus, the number and capacitance of Slave devices, the pull-up resistance of all devices (Master & Slave), and the required time constant of the system, respectively.

V_{CC} voltage must be properly stabilized by external capacitor: capacitor of min. 8 μF (ESR < 1 Ω).

Overall Functional Description

LIN is a serial communication protocol that efficiently supports the control of mechatronic nodes in distributed automotive applications. The domain is class-A multiplex buses with a single master node and a set of slave nodes.

NCV7420 is designed as a master or slave node for the LIN communication interface with an integrated 3.3 V or 5 V voltage regulator having a current capability up to 50 mA for supplying any external components (microcontroller).

NCV7420 contains the LIN transmitter, LIN receiver, voltage regulator, power-on-reset (POR) circuits and thermal shutdown (TSD). The LIN transmitter is optimized for the maximum specified transmission speed of 20 kBaud

with EMC performance due to reduced slew rate of the LIN output.

The junction temperature is monitored via a thermal shutdown circuit that switches the LIN transmitter and voltage regulator off when temperature exceeds the TSD trigger level.

NCV7420 has four operating states (normal mode, low slope mode, standby mode, and sleep mode) that are determined by the input signals EN, WAKE, STB, and TxD.

Operating States

NCV7420 provides four operating states, two modes for normal operation with communication, one standby without communication and one low power mode with very low current consumption. See Figure 3.

Figure 3. State Diagram

Table 5. MODE SELECTION

Mode	V _{CC}	RxD	INH	LIN	30 kΩ on LIN	Note
Normal – Slope	ON	Low = Dominant State High = Recessive State	High if STB=High during state transition; Floating otherwise	Normal Slope	ON	(Note 7)
Normal – Low Slope	ON	Low = Dominant State High = Recessive State	High if STB=High during state transition; Floating otherwise	Low Slope	ON	(Note 8)
Standby	ON	Low after LIN wake-up, high otherwise	Floating	OFF	OFF	(Notes 9 and 10)
Sleep	OFF	Clamped to V _{CC}	Floating	OFF	OFF	

- The normal slope mode is entered when pin EN goes HIGH while TxD is in HIGH state during EN transition.
- The low slope mode is entered when pin EN goes HIGH while TxD is in LOW state during EN transition. LIN transmitter gets on only after TxD returns to high after the state transition.
- The standby mode is entered automatically after power-up.
- In standby mode, RxD High state is achieved by internal pull-up resistor to V_{CC} .

Normal Slope Mode

In normal slope mode the transceiver can transmit and receive data via LIN bus with speed up to 20 kbaud. The transmit data stream of the LIN protocol is present on the TxD pin and converted by the transmitter into a LIN bus signal with controlled slew rate to minimize EMC emission. The receiver consists of the comparator that has a threshold with hysteresis in respect to the supply voltage and an input filter to remove bus noise. The LIN output is pulled HIGH via an internal 30 kΩ pull-up resistor. For master applications it is needed to put an external 1 kΩ resistor with a serial diode between LIN and V_{BB} (or INH). See Figure 2. The mode selection is done by EN=HIGH when TxD pin is

HIGH. If STB pin is high during the standby-to-normal slope mode transition, INH pin is pulled high. Otherwise, it stays floating.

Low Slope Mode

In low slope mode the slew rate of the signal on the LIN bus is reduced (rising and falling edges of the LIN bus signal are longer). This further reduces the EMC emission. As a consequence the maximum speed on the LIN bus is reduced up to 10 kbaud. This mode is suited for applications where the communication speed is not critical. The mode selection is done by EN=HIGH when TxD pin is LOW. In order not to transmit immediately a dominant state on the bus (because

TxD=LOW), the LIN transmitter is enabled only after TxD returns to HIGH. If STB pin is high during the standby-to-low slope mode transition, INH pin is pulled high. Otherwise, it stays floating.

Standby Mode

The standby mode is always entered after power-up of the NCV7420. It can also be entered from normal mode when the EN pin is low and the standby pin is high. From sleep mode it can be entered after a local wake-up or LIN wake-up. In standby mode the V_{CC} voltage regulator for supplying external components (e.g. a microcontroller) stays active. Also the LIN receiver stays active to be able to detect a remote wake-up via bus. The LIN transmitter is disabled and the slave internal termination resistor of 30 kΩ between LIN and V_{BB} is disconnected in order to minimize current consumption. Only a pull-up current source between V_{BB} and LIN is active.

Sleep Mode

The Sleep Mode provides extreme low current consumption. This mode is entered when both EN and STB pins are LOW coming from normal mode. The internal termination resistor of 30 kΩ between LIN and V_{BB} is disconnected and also the V_{CC} regulator is switched off to minimize current consumption.

Wake-up

NCV7420 has two possibilities to wake-up from sleep or standby mode (see Figure 3):

- Local wake-up: enables the transition from sleep mode to standby mode
- Remote wake-up via LIN: enables the transition from sleep- to standby mode and can be also detected when already in standby mode.

A local wake-up is **only** detected in sleep mode if a transition from LOW to HIGH or from HIGH to LOW is seen on the WAKE pin.

Figure 4. Local Wake-up Signal

A remote wake-up is **only** detected if a combination of (1) a falling edge at the LIN pin (transition from recessive to dominant) is followed by (2) a dominant level maintained

for a time period > t_{WAKE} and (3) again a rising edge at pin LIN (transition from dominant to recessive) happens.

Figure 5. Remote Wake-up Behavior

The wake-up source is distinguished by pin RxD in the standby mode:

- RxD remains HIGH after power-up or local wake-up.

- RxD is kept LOW until normal mode is entered after a remote wake-up (LIN).
