3.3V 100/133 MHz Differential 1:19 HCSL Clock ZDB/Fanout Buffer for PCIe®

Description

The NB3N1900K differential clock buffers are designed to work in conjunction with a PCIe compliant source clock synthesizer to provide point-to-point clocks to multiple agents. The device is capable of distributing the reference clocks for Intel® QuickPath Interconnect (Intel QPI & UPI), PCIe Gen1, Gen2, Gen3, Gen4. The NB3N1900K internal PLL is optimized to support 100 MHz and 133 MHz frequency operation. The NB3N1900K supports HCSL output levels.

Features

- Fixed Feedback Path for Lowest Input-to-Output Delay
- Eight Dedicated OE# Pins for Hardware Control of Outputs
- PLL Bypass Configurable for PLL or Fanout Operation
- Selectable PLL Bandwidth
- Spread Spectrum Compatible: Tracks Input Clock Spreading for Low EMI
- SMBus Programmable Configurations
- 100 MHz and 133 MHz PLL Mode to Meet the Next Generation PCIe Gen2/Gen3/Gen4 and Intel QPI & UPI Phase Jitter
- 2 Tri-Level Addresses Selection (Nine SMBUS Addresses)
- Cycle-to-Cycle Jitter: < 50 ps
- Output-to-Output Skew: < 65 ps
- Input-to-Output Delay: Fixed at 0 ps
- Input-to-Output Delay Variation: < 50 ps
- Phase Jitter: PCIe Gen3 < 1 ps rms
- Phase Jitter: PCIe Gen4 < 0.5 ps rms
- Phase Jitter: QPI 9.6GB/s < 0.12 ps rms
- QFN 72-pin Package, 10 mm x 10 mm
- These are Pb-Free Devices

Table 7. PIN DESCRIPTION

Pin #	Pin Name	Pin Type	Description
1	VDDA	PWR	3.3 V power for the PLL core.
2	GND A	PWR	Ground pin for the PLL core.
3	IREF	OUT	This pin establishes the reference for the differential current-mode output pairs. It requires a fixed precision resistor to ground. 475 Ω is the standard value for 100 Ω differential impedance. Other impedances require different values. See data sheet.
4	100M_133M#	IN	Input to select operating frequency 1 = 100.00 MHz, 0 = 133.33 MHz
5	HBW_BY_P_LBW#	IN	Trilevel input to select High BW, Bypass or Low BW mode. See PLL Operating Mode Table for Details.
6	PWRGD/PWRDN#	IN	Notifies device to sample latched inputs and start up on first high assertion, or exit Power Down Mode on subsequent assertions. Low enters Power Down Mode.
7	GND	PWR	Ground pin.
8	VDDR	PWR	3.3 V power for differential input clock (receiver). This VDD should be treated as an analog power rail and filtered appropriately.
9	CLK_IN	IN	0.7 V Differential true input
10	CLK_IN#	IN	0.7 V Differential complementary Input
11	SA_0	IN	SMBus address bit. This is a tri-level input that works in conjunction with the SA_1 to decode 1 of 9 SMBus Addresses.
12	SDA	I/O	Data pin of SMBus circuitry, 5V tolerant
13	SCL	IN	Clock pin of SMBus circuitry, 5V tolerant
14	SA_1	IN	SMBus address bit. This is a tri-level input that works in conjunction with the SA_0 to decode 1 of 9 SMBus Addresses.
15	NC	N/A	No Connection.
16	NC	N/A	No Connection.
17	FB_OUT#	OUT	Complementary half of differential feedback output, provides feedback signal to the PLL for synchronization with input clock to eliminate phase error.
18	FB_OUT	OUT	True half of differential feedback output, provides feedback signal to the PLL for synchronization with the input clock to eliminate phase error.
19	DIF0	OUT	0.7 V differential true clock output

ΔV_{cross}	Crossing Voltage (var) (Notes 11 and 16)	Scope averaging off			140	mV

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

11. Guaranteed by design and characterization, not tested in production. $I_{REF} = V_{DD}/(3 \times R_{REF})$. For $R_{REF} = 475\ \Omega$ (1%), $I_{REF} = 2.32\text{ mA}$. $I_{OH} = 6 \times I_{REF}$ and $V_{OH} = 0.7\text{ V}$ @ $Z_O = 50\ \Omega$ (100 Ω differential impedance).

12. Measured from differential waveform.

13. Slew rate is measured through the Vswing voltage range centered around differential 0 V. This results in a $\pm 150\text{ mV}$ window around differential 0 V.

14. Matching applies to rising and falling edge rate of differential waveform. It is measured using a $\pm 75\text{ mV}$ window centered on the average cross point where the clock rising meets clock# falling. The median cross point is used to calculate voltage thresholds that the oscilloscope uses to calculate the slew rate. Measurement taken using a 100 Ω differential impedance 5" trace PCB.

15. Vcross is defined as voltage where Clock = Clock# measured on a component test board and only applies to the differential rising edge (i.e. Clock rising and Clock# falling).

16. The total variation of all Vcross measurements in any particular system. Note that this is a subset of V_{cross_min}/max (V_{cross} absolute) allowed. The intent is to limit Vcross induced modulation by setting V_{cross_delta} to be smaller than V_{cross} absolute.

17. Measured from single-ended waveform

18. Measured with scope averaging off, using statistics function. Variation is difference between min and max.

$t_{jyc-cyc}$	Jitter, Cycle to cycle (Notes 20, 27 and 30)	PLL mode			50	ps
		Additive Jitter in Bypass Mode			50	ps

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

20. Measured into fixed 2 pF load cap. Input to output skew is measured at the first output edge following the corresponding input.

21. Measured from differential cross-point to differential cross-point. This parameter can be tuned with external feedback path, if present.

22. All Bypass Mode Input-to-Output specs refer to the timing between an input edge and the specific output edge created by it.

23. This parameter is deterministic for a given device.

24. Measured with scope averaging on to find mean value. CLK_IN slew rate must be matched to DIF output slew rate.

25. t is the period of the input clock.

26. Measured as maximum pass band gain. At frequencies within the loop BW, highest point of magnification is called PLL jitter peaking.

27. Guaranteed by design and characterization, not tested in production.

28. Measured at 3 db down or half power point.

29. Duty cycle distortion is the difference in duty cycle between the output and the input clock when the device is operated in bypass mode. @ 100.00 MHz.

30. Measured from differential waveform.

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

31. Applies to all outputs.

32. See <http://www.pcisig.com> for complete specs

33. Sample size of at least 100K cycles. This figures extrapolates to 108 ps pk-pk @ 1M cycles for a BER of 1-12.

34. Calculated from Intel-supplied Clock Jitter Tool v 1.6.3.

35. For RMS figures, additive jitter is calculated by solving the following equation: (Additive jitter)² = (total jitter)² - (input jitter)²

36. Guaranteed by design and characterization, not tested in production

PWRGD/PWRDN#

PWRGD/PWRDN# is a dual function pin. PWRGD is asserted high and de-asserted low. De-assertion of PWRGD (pulling the signal low) is equivalent to indicating a powerdown condition. PWRGD (assertion) is used by the NB3N1900K to sample initial configurations such as frequency select condition and SA selections.

After PWRGD has been asserted high for the first time, the pin becomes a PWRDN# (Power Down) pin that can be used to shut off all clocks cleanly and instruct the device to invoke power savings mode. PWRDN# is a completely asynchronous active low input. When entering power savings mode, PWRDN# should be asserted low **prior to shutting off the input clock or power** to ensure all clocks shut down in a glitch free manner. When PWRDN# is

asserted low by two consecutive rising edges of DIF#, all differential outputs are held tri-stated on the next DIF# high to low transition. The assertion and de-assertion of PWRDN# is absolutely asynchronous.

WARNING: Disabling of the CLK_IN input clock prior to assertion of PWRDN# is an undefined mode and not recommended. Operation in this mode may result in glitches, excessive frequency shifting, etc.

0	Tri-state	Tri-state

Buffer Power-Up State Machine

Table 20. BUFFER POWER-UP STATE MACHINE

State	Description
0	3.3 V Buffer power off
1	After 3.3 V supply is detected to rise above 3.135 V, the buffer enters State 1 and initiates a 0.1 ms–0.3 ms delay.
2	Buffer waits for a valid clock on the CLK input and PWRDN# de-assertion (or PWRGD assertion low to high)
3	Once the PLL is locked to the CLK_IN input clock, the buffer enters state 3 and enables outputs for normal operation. (Notes 46, 47)

46. The total power up latency from power on to all outputs active must be less than 1.8 ms (assuming a valid clock is present on CLK_IN input).
 47. If power is valid and powerdown is de-asserted (PWRGD asserted) but no input clocks are present on the CLK_IN input, DIF clocks must remain disabled. Only after valid input clocks are detected, valid power, PWRDN# de-asserted (PWRGD asserted) with the PLL locked/stable and the DIF outputs enabled.

Figure 4. Buffer Power-Up State Diagram

Device Power-Up Sequence

Follow the power-up sequence below for proper device functionality:

1. PWRGD/PWRDN# pin must be Low.
2. Assign remaining control pins to their required state (100M_133M#, HBW_BYPASS_LBW#, SDA, SCL)

3. Apply power to the device.

4. Once the VDD pin has reached a valid VDDmin level (3.3V -5%), the PWRGD/PWRDN# pin must be asserted High. See Figure 5.

Note: If no clock is present on the CLK_IN/CLK_IN# pins when device is powered up, there will be no clock on DIF/DIF# outputs.

GENERAL SMBUS SERIAL INTERFACE INFORMATION FOR THE NB3N1900K

How to Write:

- Controller (host) sends a start bit.
- Controller (host) sends the write address $XX_{(H)}$
- Clock(device) will **acknowledge**
- Controller (host) sends the beginning byte location = N
- Clock(device) will **acknowledge**
- Controller (host) sends the data byte count = X
- Clock(device) will **acknowledge**
- Controller (host) starts sending **Byte N through Byte N + X - 1**
- Clock(device) will **acknowledge** each byte **one at a time**
- Controller (host) sends a Stop bit

- Clock(device) will **acknowledge**
- Controller (host) sends the beginning byte location = N

- Clock(device) will **acknowledge**
- Controller (host) will send a separate start bit.
- Controller (host) sends the read address $YY_{(H)}$
- Clock(device) will **acknowledge**
- vclock will send the data byte count = X
- Clock(device) sends **Byte N + X - 1**
- Clock(device) sends **Byte 0 through byte X (if $X_{(H)}$ was written to byte 8)**.
- Controller (host) will need to acknowledge each byte
- Controller (host) will send a not acknowledge bit
- Controller (host) sends a Stop bit
