

## Half-Bridge N-Channel MOSFET Driver for DC/DC Conversion

### DESCRIPTION

SiP41105 is a high-speed half-bridge MOSFET driver with adaptive shoot-through protection for use in high frequency, high current, multiphase dc-dc synchronous rectifier buck power supplies. It is designed to operate at switching frequencies up to 1 MHz. The high-side driver is bootstrapped to allow driving N-channel MOSFETs. SiP41105 comes with adaptive shoot-through protection to prevent simultaneous conduction of the external MOSFETs.

The SiP41105 is available in a 16 pin TSSOP PowerPAK® package and is specified to operate over the industrial temperature range of - 40 °C to 85 °C.

### FEATURES

- 5 V gate drive
- Undervoltage lockout
- Internal bootstrap diode
- Adaptive shoot-through protection
- Synchronous MOSFET enable
- Shutdown control
- Adjustable highside propagation delay
- Switching frequency up to 1 MHz
- Drive MOSFETs In 4.5 V to 50 V systems

### APPLICATIONS

- Multi-phase DC/DC conversion
- High current synchronous buck converters
- High frequency synchronous buck converters
- Asynchronous-to-synchronous adaptations
- Mobile computer DC/DC converters
- Desktop computer DC/DC converters

**DETAILED OPERATION**

**PWM**

The PWM pin controls the switching of the external MOSFETs. The driver logic operates in a noninverting configuration. The PWM input stage should be driven by a signal with fast transition times, like those provided by a PWM controller or logic gate, (< 200 ns). The PWM input functions as a logic input and is not intended for applications where a slow changing input voltage is used to generate a switching output when the input switching threshold voltage is reached.

**Low-Side Driver**

The supplies for the low-side driver are V<sub>DD</sub> and GND. During shutdown, OUT<sub>L</sub> is held low.

**High-Side Driver**

The high-side driver is isolated from the substrate to create a floating high-side driver so that an N-Channel MOSFET can be used for the high-side switch. The supplies for the high-side driver are BOOT and LX. The voltage is supplied by a floating bootstrap capacitor, which is continually recharged by the switching action of the output. During shutdown OUT<sub>H</sub> is held low.

**Bootstrap Circuit**

The internal bootstrap diode and a bootstrap capacitor form a charge pump that supplies voltage to the BOOT pin. An integrated bootstrap diode replaces the external Schottky

diode needed for the bootstrap circuit; only a capacitor is necessary to complete the bootstrap circuit. The bootstrap capacitor is sized according to,

$$C_{BOOT} = (Q_{GATE} / \Delta V_{BOOT - LX}) \times 10$$

where Q<sub>GATE</sub> is the gate charge needed to turn on the high-side MOSFET and ΔV<sub>BOOT - LX</sub> is the amount of droop allowed in the bootstrapped supply voltage when the high-side MOSFET is driven high. The bootstrap capacitor value is typically 0.1 μF to 1 μF. The bootstrap capacitor voltage rating must be greater than V<sub>DD</sub> + 5 V to withstand transient spikes and ringing.

**Shoot-Through Protection**

The external MOSFETs are prevented from conducting at the same time during transitions. Break-before-make circuits monitor the voltages on the LX pin and the OUT<sub>L</sub> pin and control the switching as follows: When the signal on PWM goes low, OUT<sub>H</sub> will go low after an internal propagation delay. After the voltage on LX falls below 1 V by the inductor action, the low-side driver is enabled and OUT<sub>L</sub> goes high after some delay. When the signal on PWM goes high, OUT<sub>L</sub> will go low after an internal propagation delay. After the voltage on OUT<sub>L</sub> drops below 1 V the high-side driver is enabled and OUT<sub>H</sub> will go high after an internal propagation delay. If LX does not drop below 1 V within 400 ns after OUT<sub>H</sub> goes low, OUT<sub>L</sub> is forced high until the next PWM transition.

### Delay

The addition of a capacitor between DELAY and GND will increase the propagation delay time for OUTH going high. Delay capacitance may be added to prevent shoot through current in the low-side MOSFET due to the finite time between OUT<sub>L</sub> going low and the continuing conduction of the low-side MOSFET. Choose a MOSFET with lower gate resistance to reduce this effect. If necessary, choose a capacitor value that prevents MOSFET conduction under worst-case temperature and manufacturing conditions. Propagation delay is increased according to the ratio of 1.2 ns/pF.

### Synchronous MOSFET Enable

Under light load conditions, efficiency can be increased by disabling the synchronous MOSFET, thus avoiding the gate charge losses of the synchronous MOSFET. When EN<sub>SYNC</sub> is low, OUT<sub>L</sub> is forced low. When high, the low-side driver operates normally. ENSYNC should be driven by a 5 V signal.

### Shutdown

The driver enters shutdown mode when  $\overline{SD}$  is low. Shutdown current is less than 1  $\mu$ A.

### V<sub>DD</sub> Bypass Capacitor

MOSFET drivers draw large peak currents from the supplies when they switch. A local bypass capacitor is required to supply this current and reduce power supply noise. Connect a 1  $\mu$ F ceramic capacitor as close as practical between the V<sub>DD</sub> and GND pins.

### Undervoltage Lockout

Undervoltage lockout prevents control of the circuit until the supply voltages reach valid operating levels. The UVLO circuit forces OUT<sub>L</sub> and OUT<sub>H</sub> to low when V<sub>DD</sub> is below its specified voltage. A separate UVLO forces OUT<sub>H</sub> low when the voltage between BOOT and LX is below the specified voltage.

### Thermal Protection

If the die temperature rises above 165 °C, the thermal protection disables the drivers. The drivers are re-enabled after the die temperature has decreased below 140 °C.
