

Ignition coil driver power I.C.

Datasheet - production data

- Battery fault tolerant pins
- ESD protected
- TTL compatible

Description

VBG08H is a single channel driver, plus an IGBT power stage internally assembled using Chip On Chip (COC) hybrid technology.

The two chips are assembled together in the OctaPAK[®] package.

The device comes with several built-in protections like a coil current limiter, thermal monitoring circuit, which triggers a Soft Shut Down (SSD) as soon as the maximum allowable temperature is reached (TSD). It avoids extra voltage on the secondary side of the coil transformer.

The Slow Turn On circuit (STO), avoids unwanted sparks during first negative dV/dt of HVC voltage at turn on.

The current flag circuit provides an output logical signal voltage when the coil current reaches a fixed threshold.

Features

HV _{CL}	I _{NOM}	V _S	I _S
360 V	8 A ⁽¹⁾	6 - 40 V	5 mA

1. Max operative current

- Smart electronic ignition with embedded IGBT power stage
- Coil current limiter
- Current threshold flag diagnostic output
- Enable pin
- Slow turn-on
- Soft shut down (SSD) operated by low voltage clamp circuit (LVC)
- SSD activated by
 - Thermal intervention ($T_j > 150^\circ\text{C}$)
 - Enable pin
 - Input overvoltage
 - Battery overvoltage

1 Detailed description

VBG08H is a single channel driver, plus an IGBT power stage internally assembled using Chip On Chip (COC) hybrid technology. The Power Stage integrates the current shunt resistor for sensing the coil current, and the thermal diode for monitoring the temperature which triggers the TSD intervention.

The two chips are assembled together in the OctaPAK[®] package. The device is intended for driving huge inductive loads in harsh automotive environments (as electronic ignitions). The functional block diagram is shown in [Figure 1](#).

The IGBT is controlled by the input signals pin INP. In particular, when the device is enabled (EN pin is at "0"), the transition low to high of INP pin turns-on the IGBT, while, the transition high to low of the same input signal, turns-off the IGBT causing an extra voltage on the secondary side of the coil transformer, generating a spark in the spark system plug.

The implemented features offer a specific design advantage that makes the VBG08H particularly suitable for E.C.U. applications.

The device comes with several built-in protections like a coil current limiter, a thermal monitoring circuit, which triggers a Soft Shut Down (SSD) as soon as the maximum allowable temperature is reached (TSD), avoiding to generate an extra voltage on the secondary side of the coil transformer.

Soft shut down is performed using a Low Voltage Clamp (LVC) circuit, which clamps the primary coil winding at a fixed voltage, with respect to the battery value: LVC is activated as the result of a logical OR combination among different fault conditions: thermal shutdown, input overvoltage, internal wire bonding disconnection, supply overvoltage, device disabling in ON-state (EN pin pulled high while INP pin is high).

All these fault events trigger the soft shut down operation and cause a slow discharge of the coil current, avoiding generating any undesired sparks.

If SSD is activated by TSD, the complete slow coil current discharge depends on the duration of input signal in the high state. If the input signal is high for a time longer than the coil discharge time, the SSD stays activated until the coil is completely discharged (zero coil current).

Anyway, if the input command signal arrives while the SSD is active, the LVC is immediately disabled for allowing the spark generation with the residual energy.

SSD timing diagrams are shown in [Figure 7](#), [Figure 8](#) and [Figure 9](#).

In case of thermal intervention, the IGBT remains switched off until the internal junction temperature, decreasing, reaches a lower temperature threshold, which corresponds to the fixed temperature hysteresis. In addition to the built-in protections above described, the chip is equipped with a single current flag diagnostic output.

Current Flag circuit provides an output logical signal voltage, which goes low (after a filtering time) when the input control pin goes high, and returns high when the coil current reaches a fixed value threshold. An internal voltage regulator, connected to the battery pin V_S supplies all the internal circuitry.

The EN pin is intended as chip enable pin and it is used for enabling / disabling the device (see [Figure 6](#)).

The event "EN pulled high" is stored inside internal register and causes the complete slow discharge of coil current.

Device can restart when the EN pin is pulled low and after the first low to high transition of the input pin. [Figure 12](#), [Figure 13](#), [Figure 14](#) and [Figure 15](#), show device behavior, with different combinations of INP and EN signal pins. This pin is provided with an internal pull-up current source, which disables the chip by default, in case the pin is left floating.

1.1 Slow turn-on

Device is internally equipped with a completely integrated Slow Turn On circuit (STO), that helps avoiding unwanted sparks during first negative dV/dt of HVC voltage at turn on (see [Figure 5](#)).

1.2 Input over voltage (INP_OV)

Device is internally equipped with a built in protection which is activated in case of command input pin over voltage. If the input pin is shorted with a supply voltage (V_{BATT} or V_S), which is above the internal fixed threshold "INP_OV_TH_H", the device operates a soft shutdown which slowly discharges the coil current. This event is managed by the device as a "real time event", so the completion of coil current discharge depends on the time duration of the INP_OV detection. As soon as the INP_OV condition is removed (voltage at input pin decreases below the second lower threshold voltage "INP_OV_TH_H - INP_OV_HYS"), the device can be switched on, if a normal high state voltage is applied on the command input pin. See [Figure 16](#) for more details.

1.3 Battery overvoltage

When the supply voltage V_S overcomes the " $V_{S_OFF_TH}$ " (battery load dump) for a time longer than 220 μs (typ), the device operates a soft shutdown until the complete coil current discharge. The device remains switched off until the battery voltage falls under the second lower threshold voltage, which corresponds to the prefixed hysteresis parameter " $V_{S_OFF_HYS}$ ".

Once this condition is verified, only a low to high transition of command input pin can turn on the device. See [Figure 17](#) for more details.

Table 2. Pin name and function

Pin number	Pin name	Pin function
1	PGND1	Power GND
2	INP	Input control pin / pulled down if left floating
3	V _S	Battery supply voltage
4	EN	Chip enable control pin / pulled up if left floating
5	GND	Controller GND
6	C.F.	Current flag output / open drain
7	PGND2	Power GND
TAB	HVC	IGBT HV collector

Type	Description	Value
R1	C _{Flag} filter resistor	1 K
R2	C _{Flag} filter resistor	≥ 4 K
C1	V _{CC} capacitor	100 nF
C2	V _{CC} capacitor	10 μF
C3	C _{Flag} filter capacitor	(1)

1. Application dependent.

3.1 Absolute maximum ratings

Stressing the device above the ratings listed in [Table 4](#) may cause permanent damage to the device itself. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the operating sections of this specification is not implied. Exposure to the conditions reported in this section for extended periods may affect device reliability.

Table 4. Absolute maximum ratings⁽¹⁾

Symbol	Parameter	Value	Unit
V _{HVC}	Collector voltage (internally limited)	-16 to V _{clamp}	V
I _{HVC}	Collector current (internally limited)	Internally limited	A
V _S	I.C. supply voltage range	-0.3 to 40	V
V _{INP}	Input voltage	-0.3 to 28	V
V _{CF}	Current flag output voltage	-0.3 to 5.5	V
I _{CF}	Flag output current	1.5	mA
V _{EN}	Enable voltage	-0.3 to 28	V
ESCIS25	Single pulse SCIS energy (T _j = 25°C; L = 6 mH)	265	mJ
ESCIS150	Single pulse SCIS energy (T _j = 150°C; L = 6 mH)	175 ⁽²⁾	mJ
V _{ESD}	ESD voltage (HVC pin) (HBM: R = 1.5 KΩ; C = 100 pF)	4	KV
V _{ESD}	ESD voltage (all pins) (HBM: R = 1.5 KΩ; C = 100 pF)	2	KV
T _j	Operating junction temperature	-40 to 175	°C
T _{stg}	Storage temperature range	-55 to 175	°C
I _{(HVC)_UNDGND}	Max underground collector current (t _{app} ≤ 100 μs)	-6	A
t _{SC_MAX}	Short circuit withstand time R _{SC} = 0 Ω; I _{HVC} = 10.5 A (maximum current limitation) – V _S up to 16 V – 16 V < V _S ≤ 24 V – 24 < V _S ≤ 28V	No constrains 5 2	ms ms

1. Refer to [Figure 3](#) for voltage or currents conventions.
2. In case of the device switch-off occurs in current limitation with open secondary condition, the energy limit must not be exceeded. The double fault condition is not provided.

3.2 Thermal data

Table 5. Thermal data (estimated)

4 Electrical transient requirements

4.1 General setup

All ISO pulses are performed according to the following schematics (see [Figure 20](#) and [Figure 21](#)).

All ground pins (PGND1, GND and PGND2) are connected together as short as possible on the test board. The other pins (INP, EN, CF) are left open.

The load resistor is a nominal resistor 2 Ω. For breakdown level, for ISO1 and 2a 10 pulses are applied, and for ISO3a and 3b, test is applied during 1 minute.

Class	Content
C	All function of the device is performed as designed after exposure to disturbance
E	One or more functions of the device are not performed as designed after exposure to disturbance and cannot be returned to proper operation without replacing the device.

5 PCB layout suggestions and PGND disconnection

Device is provided with two power gnd leads perfectly symmetrical. Therefore, the current flowing through each lead is exactly half of the one flowing through coil and IGBT power stage collector. PCB power GNDs tracks must be as much symmetrical as possible respect to the Power GND node, in order to always maintain $I_{PGND1} = I_{PGND2}$ (see [Figure 4](#)).

A difference voltage V , between P_{GND1} and P_{GND2} causes a misalignment between I_{COIL_LIM} and I_{CF_TH} .

In case of only P_{GND2} disconnection the device is still operative, but its coil current is limited till a maximum value of $\frac{1}{2} I_{COIL_LIM}$. Current Flag signal operates, but its threshold value is also reduced at $\frac{1}{2} I_{CF_TH}$.

If, instead, only P_{GND1} is disconnected from the power GND, the coil current is controlled only by the width of input command signal (no limitation). Furthermore, the C.F. signal is kept in the low state for all duration of Input command signal.

6 Package and PCB thermal data

6.1 OctaPAK thermal data

Figure 22. OctaPAK on two-layers PCB

Figure 23. OctaPAK on four-layers PCB

Table 11. PCB properties

Dimension	Value
Board finish thickness	1.6 mm +/- 10%
Board dimension	78 mm x 86 mm
Board Material	FR4
Copper thickness (top and bottom layers)	0.070 mm
Copper thickness (inner layers)	0.035 mm
Thermal via separation	1.2 mm
Thermal via diameter	0.3 mm +/- 0.08 mm
Copper thickness on vias	0.025 mm
Footprint dimension	6.4 mm x 7mm
