## I<sup>2</sup>C Programmable Haptic Driver for Rotary (ERM) DC Motors

### Description

The CAT3211 is an H-Bridge motor driver IC that includes an I<sup>2</sup>C programmable haptic generator state machine, internal oscillator and adjustable LDO voltage regulator, all in one compact solution.

Two operating modes are supported: haptic mode (triggered via H\_TRIG pin or register) and vibrator mode (VIB\_EN pin or register).

H-TRIG triggers a haptic sequence where Forward, Coast, Reverse and Recovery time durations are controlled. All four timer durations are configured via I<sup>2</sup>C interface registers.

The LDO output voltage supplying the H-Bridge can be programmed from 2.0 V to 5.0 V or shorted to VIN (using LDOH register). This allows the motor to be safely overdriven for short durations, greatly increasing the user experience.

Driving VIB\_EN high sets the H-Bridge to forward direction and LDO voltage to a predefined vibrator setting (using LDOV register). The motor can be continuously and safely driven at low voltages in vibrator mode.

The device is fully protected against POS, NEG and REG short and over current conditions. Thermal shutdown protection prevents damage to the device and system during over temperature junction conditions.

UQFN12 1.7 x 2 mm package is ideal for space constrained applications.

### Features

- Haptic Generator Mode with Programmable Timers
- Internal 1 ms Oscillator  $\pm 20\%$
- 600 mA Output Drive Current
- High Speed 400 kHz I<sup>2</sup>C Interface
- Internal LDO with Mode Adjustable Output Voltage
- Supply Voltage Range from 2.7 V to 5.5 V
- Internal H-Bridge Driver (0.8  $\Omega$  typ.)
- 1 Amp Diode Clamping Capability (H-Bridge & LDO)
- Zero Current Shutdown Mode
- Thermal Shutdown and Over-current Protection
- Small 1.7 mm x 2 mm, 12-lead UQFN Package
- These Devices are Pb-Free and are RoHS Compliant

### Typical Applications

- Eccentric Rotating Mass (ERM) Motor Control
- Haptic Vibrators in Mobile Devices

Table 6. PIN DESCRIPTION

Pin No	Name	Function
1	RST	Device reset active low input.
2	SDA	I <sup>2</sup> C bidirectional data input/output, open-drain.
3	SCL	I <sup>2</sup> C clock input.
4	VIN	Supply input.
5	NEG	Connect to negative side of motor
6	PGND	Ground reference for the H-Bridge.
7	POS	Connect to positive side of motor.
8	REG	Connected to the internal LDO output.
9	OSC	External oscillator input (optional).
10	H_TRIG	External Haptic mode trigger input.
11	VIB_EN	External Vibrate mode enable input.
12	GND	Ground Reference for the device logic.

### PIN FUNCTION

**VIN** is the supply voltage input pin for the device. A small 1  $\mu$ F ceramic bypass capacitor is required in close proximity across the VIN pin and the GND pin. The normal operating supply voltage range is from 2.7 V to 5.5 V. An internal under-voltage lock-out (UVLO) circuit will disable the output drive current whenever the supply voltage falls below approximately 2.0 V. The driver should not be operated for a supply VIN below 2 V. If the supply dropped below 2.0 V and VIN is restored, the device should be re-programmed to the desired register setting.

**VIB\_EN** is the vibrate enable logic input pin used to enable the vibrate mode. The applied voltage levels required for logic high and logic low are 1.4 V and 0.4 V respectively. This allows direct connection to low voltage processors. An internal pull-down resistor of 110 k $\Omega$  exists between the VIB\_EN pin and GND. When both VIB\_EN and H\_TRIG are low, the device enters a standby mode. When the VIB\_EN pin is taken high, the H-Bridge turns on the output in forward mode where the POS pin is connected to REG (and the NEG pin to PGND). In order to protect from overdriving the motor, the internal LDO regulates the H-Bridge between VIN and 2 V according to the LDOV register. If the  $\overline{\text{RST}}$  or CHIP\_EN bit in the CONFIG register are low then VIB\_EN input is ignored.

**H\_TRIG** is the haptic logic input pin to trigger the haptic pulse sequence. The applied voltage levels required for logic high and logic low are 1.4 V and 0.4 V respectively. This allows direct connection to low voltage processors. An internal pull-down resistor of 110 k $\Omega$  exists between the H\_TRIG pin and GND. When both VIB\_EN and H\_TRIG are low, the device enters a standby mode. On H\_TRIG rising edge, the H-bridge is activated with the following haptic mode sequence: forward (POS connected to REG, NEG connected to PGND), coast (both POS and NEG disconnected), and reverse (POS connected to PGND, NEG

connected to REG). The haptic pulse timing is stored in the two registers HAPTIC\_A and HAPTIC\_B. A recovery timer prevents retriggering the haptic sequence until the recovery time is over. The recovery timer can be configured between 0 and 60 clock cycles according to the HAPTIC\_B register. The H\_Bridge input voltage can be adjusted to ‘fine tune’ the overdrive voltage by setting the internal LDO regulator voltage using the LDOH register. If H\_TRIG is triggered while VIB\_EN is high, then H\_TRIG overrides and sets off a haptic timer sequence. Once the haptic sequence is finished, the device returns to normal VIB\_EN mode (forward direction and LDOV setting voltage). If the  $\overline{\text{RST}}$  or CHIP\_EN bit in the CONFIG register are low, the H\_TRIG input is ignored.

**POS** is the positive output node of the internal H-bridge. During normal operation, this pin has a drive resistance of approx 0.4  $\Omega$  to either REG (LDO output) or to PGND, depending on the direction being selected. The maximum sourcing or sinking current at this pin is current limited to 850 mA typical. When the coast timer starts, the POS pin immediately enters a high-impedance state. During any forward/reverse transitions, the POS drive output exhibits a break-before-make interval of approximately 2  $\mu$ s, eliminating any shoot-through current spikes. Internal clamping diodes on the POS pin safely dissipate any inductive load current spikes back into PGND or REG nodes.

**NEG** is the negative output node of the internal H-bridge. During normal operation, this pin has a drive resistance of 0.4  $\Omega$  to either PGND or to REG (LDO output), depending on the direction being selected. The maximum sinking or sourcing current at this pin is current limited to 850 mA typical. When the coast timer starts, the NEG pin immediately enters a high-impedance state. During any forward/reverse transitions, the NEG drive output exhibits a break-before-make interval of approximately 2  $\mu$ s,

eliminating any shoot-through current spikes. Internal clamping diodes on the NEG pin safely dissipate any inductive load current spikes back into PGND or REG nodes.

**REG** is the LDO regulated output which is connected to the input of the H-bridge. A small 1 µF ceramic bypass capacitor is required in close proximity across the REG pin and the PGND pin. The LDO output voltage setting is stored in the LDOH or LDOV registers depending on the mode selected, haptic or vibrate respectively. The LDO regulator prevents the motor from being overdriven by reducing the amplitude of the voltage applied to the H-bridge and thus the motor.

**OSC** is the external oscillator logic input pin. The haptic timer clock can be selected from the internal oscillator (1 ms time base with ±20% accuracy) or from an external oscillator if a higher precision is required. The optional external oscillator is connected to the OSC pin. Selection of the external oscillator is done by setting the OSC register EXT\_OSC bit (B0) high (1). The external and internal oscillator frequency can be divided from 0 to 128 times via bits B1, B2 & B3 in the OSC register. When the internal oscillator is used, the OSC pin can be left unconnected. When EXT\_OSC bit is high, an internal watchdog monitors the OSC pin signal. In haptic mode, if the OSC pin rising-edge to rising-edge duration is longer than the watchdog timeout (8 ms typical) then the haptic sequence is aborted to prevent any motor damage.

**SDA** is the I<sup>2</sup>C serial data line, open-drain requiring an external pull-up resistor as defined in the I<sup>2</sup>C standard. This is a bidirectional data line allowing data to be written and read from the registers. The voltage levels required for logic high and logic low are 1.4 V and 0.4 V respectively. This allows the interface to be directly connected to low voltage processors.

**SCL** is the I<sup>2</sup>C serial clock input. The voltage levels required for logic high and logic low are 1.4 V and 0.4 V respectively. This allows the interface to be directly connected to low voltage processors.

**RST** is the reset active low input logic pin. When the pin is driven low, it resets all the internal registers to their default values and shuts down the device. Once the  $\overline{\text{RST}}$  input returns to a logic high, the device is enabled again. The voltage levels required for logic high and logic low are 1.4 V and 0.4 V respectively.

Since the device has no power-on reset logic, it is recommended that after power-up, the  $\overline{\text{RST}}$  is set low for a short time in order to reset all the registers.

**GND** is the ground reference for the input logic pins. The pin must be connected to the ground plane on the PCB.

**PGND** is the ground reference for the H-bridge switches. This pin carries the return current flowing through the H-bridge via the POS and NEG pins and must be connected to the ground plane.

**Table 7. MODE SELECTION TRUTH TABLE**

RST (Pin)	CHIP_EN (Reg)	VIB_EN (Reg or Pin)	H_TRIG (Reg or Pin)	H_REPT (Reg)	REG PIN SETTING	Operation Mode
0	X	X	X	X	OFF : WEAK PULLUP VIN	Device Shutdown (VIB_EN & H_TRIG no operation). No I <sup>2</sup> C interface programming possible.
1	0	X	X	X	OFF : WEAK PULLUP VIN	Device Standby (VIB_EN & H_TRIG no operation). I <sup>2</sup> C Interface programming possible
1	1	0	0	0	OFF : WEAK PULLUP VIN	Device Standby (Awaiting signal from VIB_EN or H_TRIG).
1	1	0	1↑	0	LDOH Register Setting	Haptic mode sequence triggered on rising H_TRIG edge.
1	1	1	0	0	LDOV Register Setting	Vibrate mode enabled on VIB_EN logic high.
1	1	1	1↑	0	LDOH Register Setting	Haptic mode triggered. Once Haptic sequence completes, device returns to vibrate mode (REG = LDOV) until next haptic rising edge.
1	1	X	X	1	LDOH Register Setting	Haptic mode repeat enabled. Haptic sequence will continuously repeat programmed sequence. Ensure recovery time is correctly programmed to prevent motor damage.

NOTE: X = DON'T CARE (Can be Logic High or Logic Low)

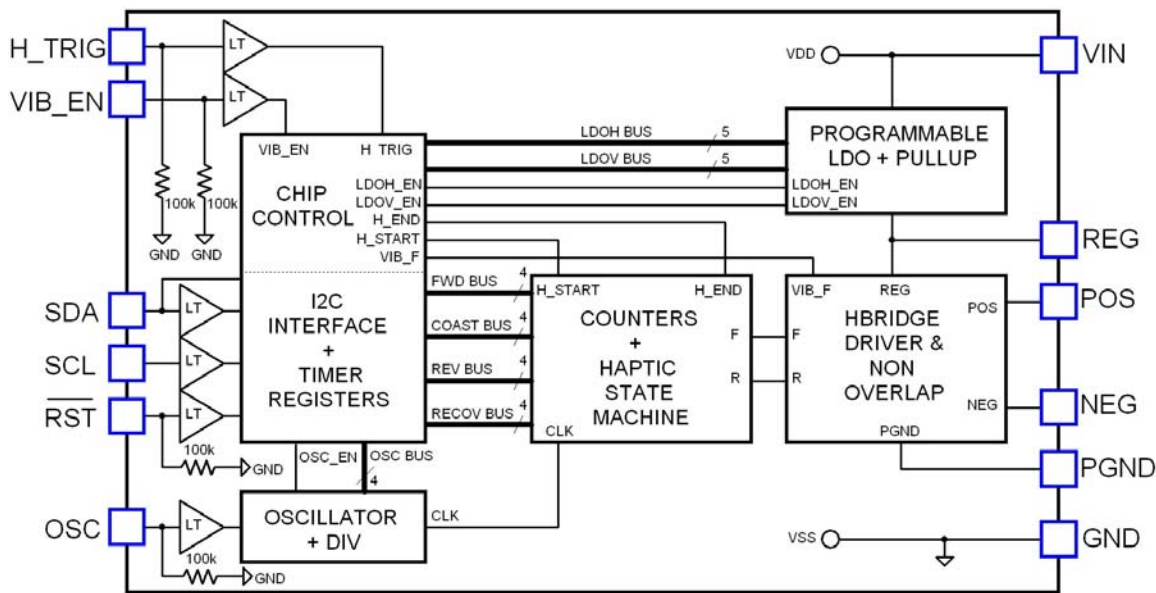

Figure 14. Simplified Block Diagram

### BASIC OPERATION

The CAT3211 contains six 8-bit registers controlled via the I<sup>2</sup>C interface. On power-up, these registers are set to their default values and can be modified to store the haptic pulse timing durations, the oscillator configuration settings, and the H-bridge regulator voltage levels in both haptic or vibrate modes.

The internal haptic sequence generator is triggered on the rising edge of H\_TRIG. This allows direct connection from a touch screen controller bypassing the CPU and improving latency time from key-press to mechanical user feedback. During the haptic mode, the voltage supply to the H-Bridge can be programmed from 2.0 V to 5.0 V or shorted to VIN via the LDOH register. This allows the motor to be safely overdriven for short durations, greatly increasing the user experience.

The device can be configured to drive the motor for a standard incoming call by driving VIB\_EN high. This mode can be driven safely for extended times since the LDO regulated voltage to rotary motor can be programmed at safe voltage levels via LDOV register.

The device can be fully shut down via the I<sup>2</sup>C interface to prevent external systems from triggering or enabling any modes by writing a zero into the CONFIG register CHIP\_EN bit (B0).

#### Haptic Mode Timers

The internal oscillator for the haptic mode timers are selected by writing a zero into the OSC register EXT\_OSC bit. Writing a one into the EXT\_OSC bit allows an external oscillator to be used via OSC pin. The internal and external clock can be further divided from 1 time to 128 times by

setting OSC\_DIV\_2, OSC\_DIV\_4 and OSC\_DIV16 accordingly.

The haptic pulse timers are configured via the HAPTIC\_A and HAPTIC\_B registers. Forward, Coast and Reverse timers can be configured from 0 to 30 clock cycles in 2 cycle increments. The Recovery timer can be configured from 0 to 60 clock cycles in 4 cycle increments. In order to prevent the motor from being overdriven in haptic mode for extended times, it is not possible to start a new haptic pulse unless the recovery time has elapsed.

#### Protection

The device includes over-current protection on all H-bridge switches to protect the POS and NEG pins from damage and stops the VIN supply from dipping due to excessive currents during fault conditions.

The device is designed to handle the inductive currents in the rotor windings during direction transitions or power off conditions without affecting operation of the device. A 1 μF capacitor is required between REG and PGND to absorb these current spikes.

In case the die temperature exceeds the thermal shutdown temperature (T<sub>SD</sub>) of 140°C typical, the CONFIG register TEMP\_L bit (B3) is set to one automatically and permanently (latched) until RST goes low. This information can be retrieved by the system by reading the CONFIG register at a later time. The TEMP\_L bit is read-only.

Thermal shutdown and under-voltage lockout disable the device if abnormal conditions are detected and dynamically enable once the abnormal condition is removed.

# CAT3211

**Table 8. REGISTER MAP**

ADD NAME	ADDR	DEFAULT	B7	B6	B5	B4	B3	B2	B1	B0

7. V\_LDO\_X voltage setting or VIN, the lesser of the two. \* default values.

**I<sup>2</sup>C Interface**

A 2-wire serial I<sup>2</sup>C-bus interfaces with the motor driver in order to program, read or write, its six registers. The SDA and SCL lines comply with the I<sup>2</sup>C electrical specification and should be terminated with external pull-up resistors. When the bus is not used, both lines are high. The device supports the maximum bus speed of 400 kbit/s. The serial bit sequence is shown below for read and write operations into

the registers. Read and write instructions are initiated by the master controller/CPU and acknowledged by the slave motor driver. The I<sup>2</sup>C address of the driver is internally fixed to the binary value 1100110. The protocol requires that the start bit and the device address are both repeated. For further details on the I<sup>2</sup>C protocol, please refer to the I<sup>2</sup>C-Bus Specification, document number 9398 393 40011, from Philips Semiconductors.

**Read Register Operation:**

**Write Register Operation:**

- S: Start condition
- R: Read bit is 1
- W: Write bit is 0
- A: Acknowledge sent by the slave motor driver (SDA low)
- A\*: Not Acknowledge sent by the master microcontroller (SDA high)
- P: Stop condition
- Slave address: Device address 7 bits (MSB first, slave address is 1100110).
- Register address: Device register address 8 bits
- Data: Data to read or write 8 bits

## APPLICATION INFORMATION

### Motor Drive

The CAT3211 can drive an external DC motor also referred to as Eccentric Rotating Mass (ERM) in haptics applications. With the H-bridge configuration, motors can be driven in the forward direction (with VIB\_EN pin high) and in forward/reverse direction (H\_TRIG edge triggered). Figure 17 shows the H-bridge block diagram and the current path for the forward motor direction. The four integrated diodes across each switch MOSFET allow for commutation of large current of inductive motor load without using external diodes. The driver response time is 40 μs typical after H\_TRIG or VIB\_EN becomes active. A vibration kick can be produced by reversing the motor spin direction to produce a sharp transient and stop the motor quickly. Due to the internal H-bridge low on-resistance, the POS and NEG terminals provide a near rail-to-rail voltage swing (due to small I · R drop) which maximizes the output

drive. When programming the LDO to a lower output voltage (REG), the motor is further protected from being overdriven. The H-bridge internal switch current limit I<sub>SC</sub> prevents the current into the motor from exceeding 850 mA typical. Depending on the motor resistance, the maximum current can be set up to 600 mA minimum.

The motor armature DC resistance (R<sub>M</sub>) sets the maximum current according to the formula below:

$$I_L = \frac{(V_{POS} - V_{NEG})}{R_M}$$

### External Component

The CAT3211 requires a small 1 μF bypass ceramic capacitor connected directly between VIN pin and GND pin, and a 1 μF between REG pin and PGND pin as shown in Figure 17.

## PACKAGE DIMENSIONS

ON Semiconductor®

UQFN12 1.7x2.0, 0.4P  
CASE 523AE-01  
ISSUE A

DATE 11 JUN 2007

SCALE 4:1

**NOTES:**

1. DIMENSIONING AND TOLERANCING PER ASME Y14.5M, 1994.
2. CONTROLLING DIMENSION: MILLIMETERS
3. DIMENSION b APPLIES TO PLATED TERMINAL AND IS MEASURED BETWEEN 0.15 AND 0.30 MM FROM TERMINAL TIP.
4. MOLD FLASH ALLOWED ON TERMINALS ALONG EDGE OF PACKAGE. FLASH 0.03 MAX ON BOTTOM SURFACE OF TERMINALS.
5. DETAIL A SHOWS OPTIONAL CONSTRUCTION FOR TERMINALS.

DIM	MILLIMETERS	
	MIN	MAX
A	0.45	0.55
A1	0.00	0.05
A3	0.127 REF	
b	0.15	0.25
D	1.70 BSC	
E	2.00 BSC	
e	0.40 BSC	
K	0.20	---
L	0.45	0.55
L1	0.00	0.03
L2	0.15 REF	

**GENERIC MARKING DIAGRAM\***

- XX = Specific Device Code
- M = Date Code
- = Pb-Free Package

\*This information is generic. Please refer to device data sheet for actual part marking. Pb-Free indicator, "G" or microdot "▪", may or may not be present.
