## Synchronous PWM Controller

The NCP3030 is a PWM device designed to operate from a wide input range and is capable of producing an output voltage as low as 0.6 V. The NCP3030 provides integrated gate drivers and an internally set 1.2 MHz (NCP3030A) or 2.4 MHz (NCP3030B) oscillator. The NCP3030 also has an externally compensated transconductance error amplifier with an internally fixed soft-start. Protection features include lossless current limit and short circuit protection, output overvoltage protection, output undervoltage protection, and input undervoltage lockout. The NCP3030 is currently available in a SOIC-8 package.

### Features

- Input Voltage Range from 4.7 V to 28 V
- 1.2 MHz Operation (NCP3030B – 2.4 MHz)
- 0.8 V Internal Reference Voltage
- Internally Programmed 1.8 ms Soft-Start (NCP3030B – 1.3 ms)
- Current Limit and Short Circuit Protection
- Transconductance Amplifier with External Compensation
- Input Undervoltage Lockout
- Output Overvoltage and Undervoltage Detection
- NCV Prefix for Automotive and Other Applications Requiring Site and Change Controls
- These are Pb-Free Devices

## PIN FUNCTION DESCRIPTION

Pin	Pin Name	Description
1	V <sub>CC</sub>	The V <sub>CC</sub> pin is the main voltage supply input. It is also used in conjunction with the VSW pin to sense current in the high side MOSFET.
2	COMP	The COMP pin connects to the output of the Operational Transconductance Amplifier (OTA) and the positive terminal of the PWM comparator. This pin is used in conjunction with the FB pin to compensate the voltage mode control feedback loop.
3	FB	The FB pin is connected to the inverting input of the OTA. This pin is used in conjunction with the COMP pin to compensate the voltage mode control feedback loop.
4	GND	Ground Pin
5	LSDR	The LSDR pin is connected to the output of the low side driver which connects to the gate of the low side N-FET. It is also used to set the threshold of the current limit circuit (I <sub>SET</sub> ) by connecting a resistor from LSDR to GND.
6	VSW	The VSW pin is the return path for the high side driver. It is also used in conjunction with the V <sub>CC</sub> pin to sense current in the high side MOSFET.
7	HSDR	The HSDR pin is connected to the output of the high side driver which connects to the gate of the high side N-FET.
8	BST	The BST pin is the supply rail for the gate drivers. A capacitor must be connected between this pin and the VSW pin.

High-Side Driver Output	HSDR	40	-0.3	V
Low-Side Driver Output	LSDR	13.2	-0.3	V
Main Supply Voltage Input	V <sub>CC</sub>	40	-0.3	V
Switch Node Voltage	V <sub>SW</sub>	40	-0.6	V
Maximum Average Current V <sub>CC</sub> , BST, HSDRV, LSDRV, V <sub>SW</sub> , GND	I <sub>max</sub>	130		mA
Operating Junction Temperature Range (Note 1)	T <sub>J</sub>	-40 to +140		°C
Maximum Junction Temperature	T <sub>J(MAX)</sub>	+150		°C
Storage Temperature Range	T <sub>stg</sub>	-55 to +150		°C
Thermal Characteristics – SOIC-8 Plastic Package (Note 2) Thermal Resistance Junction-to-Air (Note 3)	R <sub>θJA</sub>	110 165		°C/W
Lead Temperature Soldering (10 sec): Reflow (SMD styles only) Pb-Free (Note 4)	R <sub>F</sub>	260 Peak		°C

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

1. The maximum package power dissipation limit must not be exceeded.

$$P_D = \frac{T_{J(max)} - T_A}{R_{\theta JA}}$$

2. When mounted on minimum recommended FR-4 or G-10 board.
3. The value of  $\theta_{JA}$  is measured with the device mounted on minimum footprint, in still air environment with  $T_A = 25^\circ\text{C}$ . The value in any given application depends on the user's specific board design.
4. 60-180 seconds minimum above 237°C.

## DETAILED DESCRIPTION

### OVERVIEW

The NCP3030A/B operates as a 1.2/2.4 MHz, voltage mode, pulse width modulated, (PWM) synchronous buck converter. It drives high-side and low-side N-channel power MOSFETs. The NCP3030 incorporates an internal boost circuit consisting of a boost clamp and boost diode to provide supply voltage for the high side MOSFET gate driver. The NCP3030 also integrates several protection features including input undervoltage lockout (UVLO), output undervoltage (OUV), output overvoltage (OOV), adjustable high-side current limit ( $I_{SET}$  and  $I_{LIM}$ ), and thermal shutdown (TSD).

The operational transconductance amplifier (OTA) provides a high gain error signal from  $V_{out}$  which is compared to the internal 1.5 V pk-pk ramp signal to set the duty cycle converter using the PWM comparator. The high side switch is turned on by the positive edge of the clock cycle going into the PWM comparator and flip flop following a non-overlap time. The high side switch is turned off when the PWM comparator output is tripped by the modulator ramp signal reaching a threshold level established by the error amplifier. The gate driver stage incorporates fixed non-overlap time between the high-side

and low-side MOSFET gate drives to prevent cross conduction of the power MOSFET's.

### POR and UVLO

The device contains an internal Power On Reset (POR) and input Undervoltage Lockout (UVLO) that inhibits the internal logic and the output stage from operating until  $V_{CC}$  reaches its respective predefined voltage levels (4.3 V typical).

### Startup and Shutdown

Once  $V_{CC}$  crosses the UVLO rising threshold the device begins its startup process. Closed-loop soft-start begins after a 400  $\mu$ s delay wherein the boost capacitor is charged, and the current limit threshold is set. During the 400  $\mu$ s delay the OTA output is set to just below the valley voltage of the internal ramp. This is done to reduce delays and to ensure a consistent pre-soft-start condition. The device increases the internal reference from 0 V to 0.8 V in 32 discrete steps while maintaining closed loop regulation at each step. Each step contains 64 switching cycles. Some overshoot may be evident at the start of each step depending on the voltage loop phase margin and bandwidth. The total soft-start time is 1.8 ms for the NCP3030A and 1.3 ms for the NCP3030B.

Figure 20. Soft-Start Details

# NCP3030A, NCP3030B, NCV3030A, NCV3030B

## OOV and OUV

The output voltage of the buck converter is monitored at the feedback pin of the output power stage. Two comparators are placed on the feedback node of the OTA to monitor the operating window of the feedback voltage as shown in Figures 21 and 22. All comparator outputs are ignored during the soft-start sequence as soft-start is regulated by the OTA and false trips would be generated. After the soft-start period has ended, if the feedback is below the reference voltage of comparator 2 ( $V_{FB} < 0.8\text{ V}$ ),

the output is considered “undervoltage” and the device will initiate a restart. When the feedback pin voltage rises between the reference voltages of comparator 1 and comparator 2 ( $0.8 < V_{FB} < 1.0$ ), then the output voltage is considered “Power Good.” Finally, if the feedback voltage is greater than comparator 1 ( $V_{FB} > 1.0\text{ V}$ ), the output voltage is considered “overvoltage,” and the device will latch off. To clear a latch fault, input voltage must be recycled. Graphical representation of the OOV and OUV is shown in Figures 23 and 24.

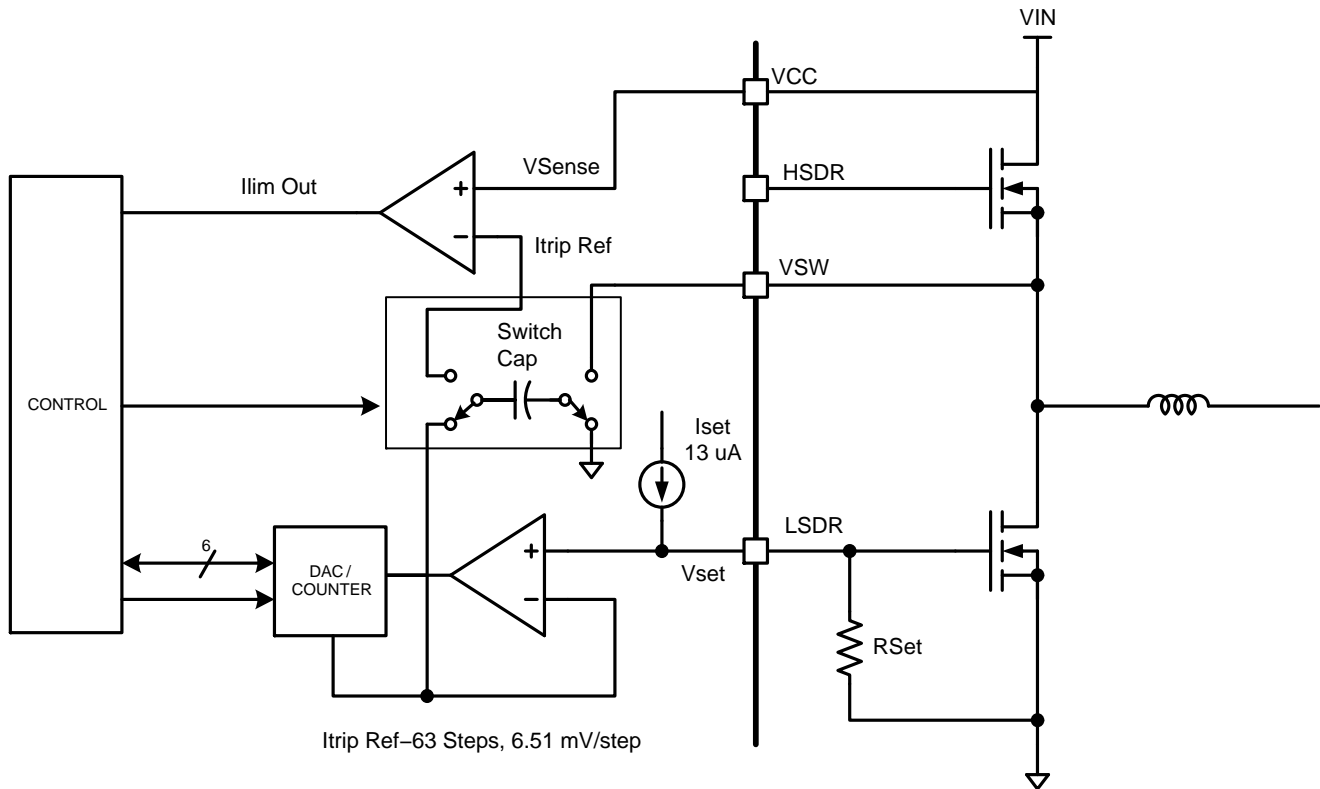

Figure 24. Powerup Sequence and Undervoltage Soft-Start

**CURRENT LIMIT AND CURRENT LIMIT SET**

**Overview**

The NCP3030 uses the voltage drop across the High Side MOSFET during the on time to sense inductor current. The

$I_{Limit}$  block consists of a voltage comparator circuit which compares the differential voltage across the  $V_{CC}$  Pin and the  $V_{SW}$  Pin with a resistor settable voltage reference. The sense portion of the circuit is only active while the HS MOSFET is turned ON.

**Figure 25.  $I_{set}$  /  $I_{Limit}$  Block Diagram**

**Current Limit Set**

The  $I_{Limit}$  comparator reference is set during the startup sequence by forcing a typically 13  $\mu A$  current through the low side gate drive resistor. The gate drive output will rise to a voltage level shown in the equation below:

$$V_{set} = I_{set} * R_{set} \quad (eq. 1)$$

Where  $I_{SET}$  is 13  $\mu A$  and  $R_{SET}$  is the gate to source resistor on the low side MOSFET.

This resistor is normally installed to prevent MOSFET leakage from causing unwanted turn on of the low side MOSFET. In this case, the resistor is also used to set the  $I_{Limit}$  trip level reference through the  $I_{Limit}$  DAC. The  $I_{set}$  process takes approximately 350  $\mu s$  to complete prior to Soft-Start stepping. The scaled voltage level across the  $I_{SET}$  resistor is converted to a 6 bit digital value and stored as the trip value. The binary  $I_{Limit}$  value is scaled and converted to the analog  $I_{Limit}$  reference voltage through a DAC counter. The DAC has 63 steps in 6.51 mV increments equating to a maximum sense voltage of 403 mV. During the  $I_{set}$  period

prior to Soft-Start, the DAC counter increments the reference on the  $I_{SET}$  comparator until it crosses the  $V_{SET}$  voltage and holds the DAC reference output to that count value. This voltage is translated to the  $I_{Limit}$  comparator during the  $I_{Sense}$  portion of the switching cycle through the switch cap circuit. See Figure 25. Exceeding the maximum sense voltage results in no current limit. Steps 0 to 10 result in an effective current limit of 0 mV.

**Current Sense Cycle**

Figure 26 shows how the current is sampled as it relates to the switching cycle. Current level 1 in Figure 26 represents a condition that will not cause a fault. Current level 2 represents a condition that will cause a fault. The sense circuit is allowed to operate below the 3/4 point of a given switching cycle. A given switching cycle's 3/4  $T_{on}$  time is defined by the prior cycle's  $T_{on}$  and is quantized in 10 ns steps. A fault occurs if the sensed MOSFET voltage exceeds the DAC reference within the 3/4 time window of the switching cycle.

Each switching cycle's Ton is counted in 10 nS time steps. The 3/4 sample time value is held and used for the following cycle's limit sample time

Figure 26.  $I_{Limit}$  Trip Point Description

**Soft-Start Current limit**

During soft-start the  $I_{SET}$  value is doubled to allow for inrush current to charge the output capacitance. The DAC reference is set back to its normal value after soft-start has completed.

**Vsw Ringing**

The  $I_{Limit}$  block can lose accuracy if there is excessive  $V_{SW}$  voltage ringing that extends beyond the 1/2 point of the high-side transistor on-time. Proper snubber design and keeping the ratio of ripple current and load current in the 10-30% range can help alleviate this as well.

**Current Limit**

A current limit trip results in completion of one switching cycle and subsequently half of another cycle  $T_{on}$  to account for negative inductor current that might have caused negative potentials on the output. Subsequently the power MOSFETs are both turned off and a 4 soft-start time period wait passes before another soft-start cycle is attempted.

**Iave vs Trip Point**

The average load trip current versus  $R_{SET}$  value is shown the equation below:

$$I_{AveTRIP} = \frac{I_{set} \times R_{set}}{R_{DS(on)}} - \frac{1}{4} \left[ \frac{V_{IN} - V_{OUT}}{L} \times \frac{V_{OUT}}{V_{IN}} \times \frac{1}{F_{SW}} \right] \quad (eq. 2)$$

Where:

L = Inductance (H)

$I_{SET} = 13 \mu A$

$R_{SET} =$  Gate to Source Resistance ( $\Omega$ )

$R_{DS(on)} =$  On Resistance of the HS MOSFET ( $\Omega$ )

$V_{IN} =$  Input Voltage (V)

$V_{OUT} =$  Output Voltage (V)

$F_{SW} =$  Switching Frequency (Hz)

**Boost Clamp Functionality**

The boost circuit requires an external capacitor connected between the BST and  $V_{SW}$  pins to store charge for supplying the high and low-side gate driver voltage. This clamp circuit limits the driver voltage to typically 7.5 V when  $V_{IN} > 9 V$ , otherwise this internal regulator is in dropout and typically  $V_{IN} - 1.25 V$ .

The boost circuit regulates the gate driver output voltage and acts as a switching diode. A simplified diagram of the boost circuit is shown in Figure 27. While the switch node is grounded, the sampling circuit samples the voltage at the boost pin, and regulates the boost capacitor voltage. The sampling circuit stores the boost voltage while the  $V_{SW}$  is high and the linear regulator output transistor is reversed biased.

Figure 27. Boost Circuit

## NCP3030A, NCP3030B, NCV3030A, NCV3030B

Reduced sampling time occurs at high duty cycles where the low side MOSFET is off for the majority of the switching period. Reduced sampling time causes errors in the regulated voltage on the boost pin. High duty cycle / input voltage induced sampling errors can result in increased boost ripple voltage or higher than desired DC boost voltage. Figure 28 outlines all operating regions.

The recommended operating conditions are shown in Region 1 (Green) where a 0.1  $\mu\text{F}$ , 25 V ceramic capacitor can be placed on the boost pin without causing damage to the device or MOSFETS. Larger boost ripple voltage occurring over several switching cycles is shown in Region 2 (Yellow).

The boost ripple frequency is dependent on the output capacitance selected. The ripple voltage will not damage the device or  $\pm 12\text{ V}$  gate rated MOSFETS.

Conditions where maximum boost ripple voltage could damage the device or  $\pm 12\text{ V}$  gate rated MOSFETS can be seen in Region 3 (Orange). Placing a boost capacitor that is no greater than 10X the input capacitance of the high side MOSFET on the boost pin limits the maximum boost voltage  $< 12\text{ V}$ . The typical drive waveforms for Regions 1, 2 and 3 (green, yellow, and orange) regions of Figure 28 are shown in Figure 29.

**Figure 29. Typical Waveforms for Region 1 (top), Region 2 (middle), and Region 3 (bottom)**

To illustrate, a 0.1  $\mu\text{F}$  boost capacitor operating at > 80% duty cycle and > 22.5 V input voltage will exceed the specifications for the driver supply voltage. See Figure 30.

Figure 30. Boost Voltage at 80% Duty Cycle

**Inductor Selection**

When selecting the inductor, it is important to know the input and output requirements. Some example conditions are listed below to assist in the process.

Table 1. DESIGN PARAMETERS

Design Parameter	Example Value
Input Voltage (V <sub>IN</sub> )	9 V to 16 V
Nominal Input Voltage (V <sub>IN</sub> )	12 V
Output Voltage (V <sub>OUT</sub> )	3.3 V
Input ripple voltage (V <sub>INRIPPLE</sub> )	300 mV
Output ripple voltage (V <sub>OUTRIPPLE</sub> )	50 mV
Output current rating (I <sub>OUT</sub> )	3 A
Operating frequency (F <sub>SW</sub> )	2.4 MHz

A buck converter produces input voltage (V<sub>IN</sub>) pulses that are LC filtered to produce a lower dc output voltage (V<sub>OUT</sub>). The output voltage can be changed by modifying the on time relative to the switching period (T) or switching frequency. The ratio of high side switch on time to the switching period is called duty cycle (D). Duty cycle can also be calculated using V<sub>OUT</sub>, V<sub>IN</sub>, the low side switch voltage drop V<sub>LSD</sub>, and the High side switch voltage drop V<sub>HSD</sub>.

$$F = \frac{1}{T} \tag{eq. 3}$$

$$D = \frac{T_{ON}}{T} (-D) = \frac{T_{OFF}}{T} \tag{eq. 4}$$

$$D = \frac{V_{OUT} + V_{LSD}}{V_{IN} - V_{HSD} + V_{LSD}} \approx D = \frac{V_{OUT}}{V_{IN}} \tag{eq. 5}$$

$$\rightarrow 27.5\% = \frac{3.3\text{ V}}{12\text{ V}}$$

The ratio of ripple current to maximum output current simplifies the equations used for inductor selection. The formula for this is given in Equation 6.

$$ra = \frac{\Delta I}{I_{OUT}} \tag{eq. 6}$$

The designer should employ a rule of thumb where the percentage of ripple current in the inductor lies between 10% and 40%. When using ceramic output capacitors the ripple current can be greater thus a user might select a higher ripple current, but when using electrolytic capacitors a lower ripple current will result in lower output ripple. Now, acceptable values of inductance for a design can be calculated using Equation 7.

$$L = \frac{V_{OUT}}{I_{OUT} \cdot ra \cdot F_{SW}} \cdot (1 - D) \rightarrow 2.2\ \mu\text{H} \tag{eq. 7}$$

$$= \frac{3.3\text{ V}}{3\text{ A} \cdot 15\% \cdot 2.4\text{ MHz}} \cdot (1 - 27.5\%)$$

The relationship between ra and L for this design example is shown in Figure 31.

**Figure 31. Ripple Current Ratio vs. Inductance**

To keep within the bounds of the parts maximum rating, calculate the RMS current and peak current.

$$I_{RMS} = I_{OUT} \cdot \sqrt{1 + \frac{ra^2}{12}} \rightarrow 3.02 \text{ A} \quad (\text{eq. 8})$$

$$= 3 \text{ A} \cdot \sqrt{1 + \frac{(0.15)^2}{12}}$$

$$I_{PK} = I_{OUT} \cdot \left(1 + \frac{ra}{2}\right) \rightarrow 3.22 \text{ A} = 3 \text{ A} \cdot \left(1 + \frac{(0.15)}{2}\right) \quad (\text{eq. 9})$$

An inductor for this example would be around 2.2 μH and should support an rms current of 3.02 A and a peak current of 3.22 A.

The final selection of an output inductor has both mechanical and electrical considerations. From a mechanical perspective, smaller inductor values generally correspond to smaller physical size. Since the inductor is often one of the largest components in the regulation system, a minimum inductor value is particularly important in space-constrained applications. From an electrical perspective, the maximum current slew rate through the output inductor for a buck regulator is given by Equation 10.

$$\text{SlewRate}_{L_{OUT}} = \frac{V_{IN} - V_{OUT}}{L_{OUT}} \rightarrow 4 \frac{\text{A}}{\mu\text{S}} = \frac{12 \text{ V} - 3.3 \text{ V}}{2.2 \mu\text{H}} \quad (\text{eq. 10})$$

This equation implies that larger inductor values limit the regulator’s ability to slew current through the output inductor in response to output load transients. Consequently, output capacitors must supply the load current until the inductor current reaches the output load current level. This results in larger values of output capacitance to maintain tight output voltage regulation. In contrast, smaller values of inductance increase the regulator’s maximum achievable slew rate and decrease the necessary capacitance, at the expense of higher ripple current. The peak-to-peak ripple current for the NCP3030A is given by the following equation:

$$I_{PP} = \frac{V_{OUT}(1 - D)}{L_{OUT} \cdot F_{SW}} \quad (\text{eq. 11})$$

I<sub>pp</sub> is the peak to peak current of the inductor. From this equation it is clear that the ripple current increases as L<sub>OUT</sub> decreases, emphasizing the trade-off between dynamic response and ripple current.

The power dissipation of an inductor consists of both copper and core losses. The copper losses can be further categorized into dc losses and ac losses. A good first order approximation of the inductor losses can be made using the DC resistance as they usually contribute to 90% of the losses of the inductor shown below:

$$LP_{CU} = I_{RMS}^2 \cdot DCR \quad (\text{eq. 12})$$

The core losses and ac copper losses will depend on the geometry of the selected core, core material, and wire used. Most vendors will provide the appropriate information to make accurate calculations of the power dissipation then the total inductor losses can be capture buy the equation below:

$$LP_{tot} = LP_{CU\_DC} + LP_{CU\_AC} + LP_{Core} \quad (\text{eq. 13})$$

### Input Capacitor Selection

The input capacitor has to sustain the ripple current produced during the on time of the upper MOSFET, so it must have a low ESR to minimize the losses. The RMS value of this ripple is:

$$I_{in\_RMS} = I_{OUT} \cdot \sqrt{D \cdot (1 - D)} \quad (\text{eq. 14})$$

D is the duty cycle, I<sub>inRMS</sub> is the input RMS current, and I<sub>OUT</sub> is the load current.

The equation reaches its maximum value with D = 0.5. Loss in the input capacitors can be calculated with the following equation:

$$P_{CIN} = ESR_{CIN} \cdot (I_{IN-RMS})^2 \quad (\text{eq. 15})$$

P<sub>CIN</sub> is the power loss in the input capacitors and ESR<sub>CIN</sub> is the effective series resistance of the input capacitance. Due to large dI/dt through the input capacitors, electrolytic or ceramics should be used. If a tantalum must be used, it must by surge protected. Otherwise, capacitor failure could occur.

### Input Start-up Current

To calculate the input startup current, the following equation can be used.

$$I_{INRUSH} = \frac{C_{OUT} \cdot V_{OUT}}{t_{SS}} \quad (\text{eq. 16})$$

I<sub>inrush</sub> is the input current during startup, C<sub>OUT</sub> is the total output capacitance, V<sub>OUT</sub> is the desired output voltage, and t<sub>SS</sub> is the soft start interval. If the inrush current is higher than the steady state input current during max load, then the input fuse should be rated accordingly, if one is used.

### Output Capacitor Selection

The important factors to consider when selecting an output capacitor is dc voltage rating, ripple current rating, output ripple voltage requirements, and transient response requirements.

The output capacitor must be rated to handle the ripple current at full load with proper derating. The RMS ratings given in datasheets are generally for lower switching frequency than used in switch mode power supplies but a multiplier is usually given for higher frequency operation. The RMS current for the output capacitor can be calculated below:

$$C_{O_{RMS}} = I_O \cdot \frac{ra}{\sqrt{12}} \quad (\text{eq. 17})$$

The maximum allowable output voltage ripple is a combination of the ripple current selected, the output capacitance selected, the equivalent series inductance (ESL) and ESR.

The main component of the ripple voltage is usually due to the ESR of the output capacitor and the capacitance selected.

$$V_{ESR\_C} = I_O \cdot ra \cdot \left( ESR_{C_0} + \frac{1}{8 \cdot F_{SW} \cdot C_0} \right) \quad (\text{eq. 18})$$

The ESL of capacitors depends on the technology chosen but tends to range from 1 nH to 20 nH where ceramic capacitors have the lowest inductance and electrolytic capacitors then to have the highest. The calculated contributing voltage ripple from ESL is shown for the switch on and switch off below:

$$V_{ESLON} = \frac{ESL \cdot I_{PP} \cdot F_{SW}}{D} \quad (\text{eq. 19})$$

$$V_{ESLOFF} = \frac{ESL \cdot I_{PP} \cdot F_{SW}}{(1 - D)} \quad (\text{eq. 20})$$

The output capacitor is a basic component for the fast response of the power supply. In fact, during load transient, for the first few microseconds it supplies the current to the load. The controller immediately recognizes the load transient and sets the duty cycle to maximum, but the current slope is limited by the inductor value.

During a load step transient the output voltage initially drops due to the current variation inside the capacitor and the ESR (neglecting the effect of the effective series inductance (ESL)).

$$\Delta V_{OUT-ESR} = \Delta I_{TRAN} \cdot ESR_{C_0} \quad (\text{eq. 21})$$

A minimum capacitor value is required to sustain the current during the load transient without discharging it. The voltage drop due to output capacitor discharge is approximated by the following equation:

$$\Delta V_{OUT-DISCHG} = \frac{(I_{TRAN})^2 \cdot L_{OUT}}{C_{OUT} \cdot (V_{IN} - V_{OUT})} \quad (\text{eq. 22})$$

In a typical converter design, the ESR of the output capacitor bank dominates the transient response. It should be noted that  $\Delta V_{OUT-DISCHARGE}$  and  $\Delta V_{OUT-ESR}$  are out of phase with each other, and the larger of these two voltages will determine the maximum deviation of the output voltage (neglecting the effect of the ESL).

Conversely during a load release, the output voltage can increase as the energy stored in the inductor dumps into the output capacitor. The ESR contribution from Equation 18 still applies in addition to the output capacitor charge which is approximated by the following equation:

$$\Delta V_{OUT-CHG} = \frac{(I_{TRAN})^2 \cdot L_{OUT}}{C_{OUT} \cdot V_{OUT}} \quad (\text{eq. 23})$$

### Power MOSFET Selection

Power dissipation, package size, and the thermal environment drive MOSFET selection. To adequately select the correct MOSFETs, the design must first predict its power dissipation. Once the dissipation is known, the thermal impedance can be calculated to prevent the specified maximum junction temperatures from being exceeded at the highest ambient temperature.

Power dissipation has two primary contributors: conduction losses and switching losses. The control or high-side MOSFET will display both switching and conduction losses. The synchronous or low-side MOSFET will exhibit only conduction losses because it switches into nearly zero voltage. However, the body diode in the synchronous MOSFET will suffer diode losses during the non-overlap time of the gate drivers.

Starting with the high-side or control MOSFET, the power dissipation can be approximated from:

$$P_{D\_CONTROL} = P_{COND} + P_{SW\_TOT} \quad (\text{eq. 24})$$

The first term is the conduction loss of the high-side MOSFET while it is on.

$$P_{COND} = (I_{RMS\_CONTROL})^2 \cdot R_{DS(on)\_CONTROL} \quad (\text{eq. 25})$$

Using the ra term from Equation 6,  $I_{RMS}$  becomes:

$$I_{RMS\_CONTROL} = I_{OUT} \cdot \sqrt{D \cdot \left( 1 + \left( \frac{ra^2}{12} \right) \right)} \quad (\text{eq. 26})$$

The second term from Equation 24 is the total switching loss and can be approximated from the following equations.

$$P_{SW\_TOT} = P_{SW} + P_{DS} + P_{RR} \quad (\text{eq. 27})$$

The first term for total switching losses from Equation 27 includes the losses associated with turning the control MOSFET on and off and the corresponding overlap in drain voltage and current.

$$P_{SW} = P_{TON} + P_{TOFF} = \frac{1}{2} \cdot (I_{OUT} \cdot V_{IN} \cdot f_{SW}) \cdot (t_{ON} + t_{OFF}) \quad (\text{eq. 28})$$

## NCP3030A, NCP3030B, NCV3030A, NCV3030B

where:

$$t_{ON} = \frac{Q_{GD}}{I_{G1}} = \frac{Q_{GD}}{(V_{BST} - V_{TH}) / (R_{HSPU} + R_G)} \quad (\text{eq. 29})$$

and:

$$t_{OFF} = \frac{Q_{GD}}{I_{G2}} = \frac{Q_{GD}}{(V_{BST} - V_{TH}) / (R_{HSPD} + R_G)} \quad (\text{eq. 30})$$

Next, the MOSFET output capacitance losses are caused by both the control and synchronous MOSFET but are dissipated only in the control MOSFET.

$$P_{DS} = \frac{1}{2} \cdot Q_{OSS} \cdot V_{IN} \cdot f_{SW} \quad (\text{eq. 31})$$

Finally the loss due to the reverse recovery time of the body diode in the *synchronous* MOSFET is shown as follows:

$$P_{RR} = Q_{RR} \cdot V_{IN} \cdot f_{SW} \quad (\text{eq. 32})$$

The low-side or synchronous MOSFET turns on into zero volts so switching losses are negligible. Its power dissipation only consists of conduction loss due to  $R_{DS(on)}$  and body diode loss during the non-overlap periods.

$$P_{D\_SYNC} = P_{COND} + P_{BODY} \quad (\text{eq. 33})$$

Conduction loss in the low-side or synchronous MOSFET is described as follows:

$$P_{COND} = (I_{RMS\_SYNC})^2 \cdot R_{DS(on)\_SYNC} \quad (\text{eq. 34})$$

where:

$$I_{RMS\_SYNC} = I_{OUT} \cdot \sqrt{(1 - D) \cdot \left(1 + \left(\frac{ra^2}{12}\right)\right)} \quad (\text{eq. 35})$$

The body diode losses can be approximated as:

$$P_{BODY} = V_{FD} \cdot I_{OUT} \cdot f_{SW} \cdot (NOL_{LH} + NOL_{HL}) \quad (\text{eq. 36})$$

**Figure 32. MOSFET Switching Characteristics**

$I_{G1}$ : output current from the high-side gate drive (HSDR)  
 $I_{G2}$ : output current from the low-side gate drive (LSDR)  
 $f_{SW}$ : switching frequency of the converter. NCP3030A is 1.2 MHz and NCP3030B is 2.4 MHz

$V_{BST}$ : gate drive voltage for the high-side drive, typically 7.5 V.

$Q_{GD}$ : gate charge plateau region, commonly specified in the MOSFET datasheet

$V_{TH}$ : gate-to-source voltage at the gate charge plateau region

$Q_{OSS}$ : MOSFET output gate charge specified in the data sheet

$Q_{RR}$ : reverse recovery charge of the low-side or synchronous MOSFET, specified in the datasheet

$R_{DS(on)\_CONTROL}$ : on resistance of the high-side, or control, MOSFET

$R_{DS(on)\_SYNC}$ : on resistance of the low-side, or synchronous, MOSFET

$NOL_{LH}$ : dead time between the LSDR turning off and the HSDR turning on, typically 85 ns

$NOL_{HL}$ : dead time between the HSDR turning off and the LSDR turning on, typically 75 ns

Once the MOSFET power dissipations are determined, the designer can calculate the required thermal impedance for each device to maintain a specified junction temperature at the worst case ambient temperature. The formula for calculating the junction temperature with the package in free air is:

$$T_J = T_A + P_D \cdot R_{\theta JA}$$

$T_J$ : Junction Temperature

$T_A$ : Ambient Temperature

$P_D$ : Power Dissipation of the MOSFET under analysis

$R_{\theta JA}$ : Thermal Resistance Junction-to-Ambient of the MOSFET's package

As with any power design, proper laboratory testing should be performed to insure the design will dissipate the required power under worst case operating conditions. Variables considered during testing should include maximum ambient temperature, minimum airflow, maximum input voltage, maximum loading, and component variations (i.e. worst case MOSFET  $R_{DS(on)}$ ).

# NCP3030A, NCP3030B, NCV3030A, NCV3030B

Figure 33. MOSFETs Timing Diagram

Another consideration during MOSFET selection is their delay times. Turn-on and turn-off times must be short enough to prevent cross conduction. If not, there will be conduction from the input through both MOSFETs to ground. Therefore, the following conditions must be met.

$$t_{d(ON)_{CONTROL}} + NOL_{LH} > t_{d(OFF)_{SYNC}} + t_{f_{SYNC}}$$

and

$$t_{(ON)_{SYNC}} + NOL_{HL} > t_{d(OFF)_{CONTROL}} + t_{f_{CONTROL}}$$

The MOSFET parameters,  $t_{d(ON)}$ ,  $t_r$ ,  $t_{d(OFF)}$  and  $t_f$  are can be found in their appropriate datasheets for specific conditions.  $NOL_{LH}$  and  $NOL_{HL}$  are the dead times which were described earlier and are 85 ns and 75 ns, respectively.

### Feedback and Compensation

The NCP3030 is a voltage mode buck converter with a transconductance error amplifier compensated by an external compensation network. Compensation is needed to achieve accurate output voltage regulation and fast transient

response. The goal of the compensation circuit is to provide a loop gain function with the highest crossing frequency and adequate phase margin (minimally 45°). The transfer function of the power stage (the output LC filter) is a double pole system. The resonance frequency of this filter is expressed as follows:

$$f_{P0} = \frac{1}{2 \cdot \pi \cdot \sqrt{L \cdot C_{OUT}}} \quad (\text{eq. 38})$$

Parasitic Equivalent Series Resistance (ESR) of the output filter capacitor introduces a high frequency zero to the filter network. Its value can be calculated by using the following equation:

$$f_{Z0} = \frac{1}{2 \cdot \pi \cdot C_{OUT} \cdot ESR} \quad (\text{eq. 39})$$

The main loop zero crossover frequency  $f_0$  can be chosen to be 1/10 – 1/5 of the switching frequency. Table 2 shows the three methods of compensation.

Table 2. COMPENSATION TYPES

Zero Crossover Frequency Condition	Compensation Type	Typical Output Capacitor Type
$f_{P0} < f_{Z0} < f_0 < f_S/2$	Type II	Electrolytic, Tantalum
$f_{P0} < f_0 < f_{Z0} < f_S/2$	Type III Method I	Tantalum, Ceramic
$f_{P0} < f_0 < f_S/2 < f_{Z0}$	Type III Method II	Ceramic

**Compensation Type II**

This compensation is suitable for electrolytic capacitors. Components of the Type II (Figure 34) network can be specified by the following equations:

**Figure 34. Type II Compensation**

$$R_{C1} = \frac{2 \cdot \pi \cdot f_0 \cdot L \cdot V_{RAMP} \cdot V_{OUT}}{ESR \cdot V_{IN} \cdot V_{ref} \cdot gm} \quad (\text{eq. 40})$$

$$C_{C1} = \frac{1}{0.75 \cdot 2 \cdot \pi \cdot f_{P0} \cdot R_{C1}} \quad (\text{eq. 41})$$

$$C_{C2} = \frac{1}{\pi \cdot R_{C1} \cdot f_S} \quad (\text{eq. 42})$$

$$R1 = \frac{V_{OUT} - V_{ref}}{V_{ref}} \cdot R2 \quad (\text{eq. 43})$$

$V_{RAMP}$  is the peak-to-peak voltage of the oscillator ramp and  $gm$  is the transconductance error amplifier gain. Capacitor  $CC2$  is optional.

**Compensation Type III**

Tantalum and ceramics capacitors have lower ESR than electrolytic, so the zero of the output LC filter goes to a higher frequency above the zero crossover frequency. This requires a Type III compensation network as shown in Figure 35.

There are two methods to select the zeros and poles of this compensation network. Method I is ideal for tantalum output capacitors, which have a higher ESR than ceramic:

**Figure 35. Type III Compensation**

$$f_{Z1} = 0.75 \cdot f_{P0} \quad (\text{eq. 44})$$

$$f_{Z2} = f_{P0} \quad (\text{eq. 45})$$

$$f_{P2} = f_{Z0} \quad (\text{eq. 46})$$

$$f_{P3} = \frac{f_S}{2} \quad (\text{eq. 47})$$

Method II is better suited for ceramic capacitors that typically have the lowest ESR available:

$$f_{Z2} = f_0 \cdot \sqrt{\frac{1 - \sin \theta \max}{1 + \sin \theta \max}} \quad (\text{eq. 48})$$

$$f_{P2} = f_0 \cdot \sqrt{\frac{1 + \sin \theta \max}{1 - \sin \theta \max}} \quad (\text{eq. 49})$$

$$f_{Z1} = 0.5 \cdot f_{Z2} \quad (\text{eq. 50})$$

$$f_{P3} = 0.5 \cdot f_S \quad (\text{eq. 51})$$

The remaining calculations are the same for both methods.

$$R_{C1} \gg \frac{2}{gm} \quad (\text{eq. 52})$$

$$C_{C1} = \frac{1}{2 \cdot \pi \cdot f_{Z1} \cdot R_{C1}} \quad (\text{eq. 53})$$

$$C_{C2} = \frac{1}{2 \cdot \pi \cdot f_{P3} \cdot R_{C1}} \quad (\text{eq. 54})$$

$$C_{FB1} = \frac{2 \cdot \pi \cdot f_0 \cdot L \cdot V_{RAMP} \cdot C_{OUT}}{V_{IN} \cdot R_{C1}} \quad (\text{eq. 55})$$

$$R_{FB1} = \frac{1}{2\pi \cdot C_{FB1} \cdot f_{P2}} \quad (\text{eq. 56})$$

$$R1 = \frac{1}{2 \cdot \pi \cdot C_{FB1} \cdot f_{Z2}} - R_{FB1} \quad (\text{eq. 57})$$

$$R2 = \frac{V_{ref}}{V_{OUT} - V_{ref}} \cdot R1 \quad (\text{eq. 58})$$

If the equation in Equation 59 is not true, then a higher value of  $R_{C1}$  must be selected.

$$\frac{R1 \cdot R2 \cdot R_{FB1}}{R1 \cdot R_{FB1} + R2 \cdot R_{FB1} + R1 \cdot R2} > \frac{1}{gm} \quad (\text{eq. 59})$$

### Special Note

The NCP3030/NCV3030 are dedicated for current sensing across high-side MOSFET via VCC pin and VSW pin, as shown in Figure 25. Therefore, the VCC pin must connect to the VIN voltage, i.e., the drain of high-side MOSFET as shown in Figure 36 above. In other words, the NCP3030/NCV3030 does not support separated VCC voltage and VIN voltage, regardless any current limit setting in LSDR pin. Using a lower VCC voltage than the VIN voltage, such as VCC=12V and VIN=20V, may damage the NCP3030/NCV3030. Disconnecting the VCC pin supply, while VIN is still presented, risks the NCP3030/NCV3030 of being damaged as well.

ON Semiconductor and  are trademarks of Semiconductor Components Industries, LLC dba ON Semiconductor or its subsidiaries in the United States and/or other countries. ON Semiconductor owns the rights to a number of patents, trademarks, copyrights, trade secrets, and other intellectual property. A listing of ON Semiconductor's product/patent coverage may be accessed at [www.onsemi.com/site/pdf/Patent-Marking.pdf](http://www.onsemi.com/site/pdf/Patent-Marking.pdf). ON Semiconductor reserves the right to make changes without further notice to any products herein. ON Semiconductor makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does ON Semiconductor assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. Buyer is responsible for its products and applications using ON Semiconductor products, including compliance with all laws, regulations and safety requirements or standards, regardless of any support or applications information provided by ON Semiconductor. "Typical" parameters which may be provided in ON Semiconductor data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. ON Semiconductor does not convey any license under its patent rights nor the rights of others. ON Semiconductor products are not designed, intended, or authorized for use as a critical component in life support systems or any FDA Class 3 medical devices or medical devices with a same or similar classification in a foreign jurisdiction or any devices intended for implantation in the human body. Should Buyer purchase or use ON Semiconductor products for any such unintended or unauthorized application, Buyer shall indemnify and hold ON Semiconductor and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that ON Semiconductor was negligent regarding the design or manufacture of the part. ON Semiconductor is an Equal Opportunity/Affirmative Action Employer. This literature is subject to all applicable copyright laws and is not for resale in any manner.
