ON Semiconductor®

To learn more about ON Semiconductor, please visit our website at
www.onsemi.com

Please note: As part of the Fairchild Semiconductor integration, some of the Fairchild orderable part numbers will need to change in order to meet ON Semiconductor's system requirements. Since the ON Semiconductor product management systems do not have the ability to manage part nomenclature that utilizes an underscore (_), the underscore (_) in the Fairchild part numbers will be changed to a dash (-). This document may contain device numbers with an underscore (_). Please check the ON Semiconductor website to verify the updated device numbers. The most current and up-to-date ordering information can be found at www.onsemi.com. Please email any questions regarding the system integration to Fairchild_questions@onsemi.com.

FOD8318

2.5 A Output Current, IGBT Drive Optocoupler with Active Miller Clamp, Desaturation Detection, and Isolated Fault Sensing

Features

- High noise immunity characterized by common mode rejection
 - 35 kV / μ s Minimum Common Mode Rejection ($V_{cm} = 1500 V_{peak}$)
- 2.5 A peak output current driving capability for most 1200 V / 150 A IGBT
- Optically isolated fault sensing feedback
- Active Miller clamp to shut off the IGBT during high dv/dt without needing a negative supply voltage
- “Soft” IGBT turn-off
- Built-in IGBT protection
 - Desaturation detection
 - Under-voltage lock out (UVLO) protection
- Wide supply voltage range from 15 V to 30 V
 - Use of P-Channel MOSFETs at output stage enables output voltage swing close to the supply rail (rail-to-rail output)
- 3.3 V / 5 V, CMOS/TTL-compatible inputs
- High Speed
 - 500 ns max. propagation delay over full operating temperature range
- Extended industrial temperature range, -40°C to 100°C temperature range
- Safety and regulatory approvals
 - UL1577, 4,243 V_{RMS} for 1 min.
 - DIN EN/IEC 60747-5-5, 1,414 V_{peak} working insulation voltage, 8000 V_{peak} transient isolation voltage ratings
- $R_{DS(ON)}$ of 1 Ω (typ.) offers lower power dissipation
- User configurable: inverting, non-inverting, auto-reset, auto-shutdown
- 8 mm creepage and clearance distances

Applications

- Industrial inverter
- Induction heating
- Isolated IGBT drive

Description

The FOD8318 is an advanced 2.5 A output current IGBT drive optocoupler capable of driving most 1200 V / 150 A IGBTs. It is ideally suited for fast-switching driving of power IGBTs and MOSFETs used in motor control inverter applications and high-performance power systems. It consists of an integrated gate drive optocoupler featuring low $R_{DS(ON)}$ CMOS transistors to drive the IGBT from rail to rail and an integrated high-speed isolated feedback for fault sensing. The FOD8318 has an active Miller clamp function to shut off the IGBT during a high dv/dt situation without the need of a negative supply voltage. It offers critical protection features necessary for preventing fault conditions that lead to destructive thermal runaway of IGBTs.

It utilizes Fairchild's proprietary Optoplanar® coplanar packaging technology and optimized IC design to achieve high noise immunity, characterized by high common mode rejection and power supply rejection specifications.

The device is housed in a compact 16-pin small outline plastic package that meets the 8 mm creepage and clearance requirements.

Truth Table

V_{IN+}	V_{IN-}	UVLO ($V_{DD2} - V_E$)	DESAT Detected?	$\overline{\text{FAULT}}$	V_{OUT}^*
X	X	Active	X	X	LOW
X	X	X	Yes	LOW	LOW
LOW	X	X	X	X	LOW
X	HIGH	X	X	X	LOW
HIGH	LOW	Not Active	No	HIGH	HIGH

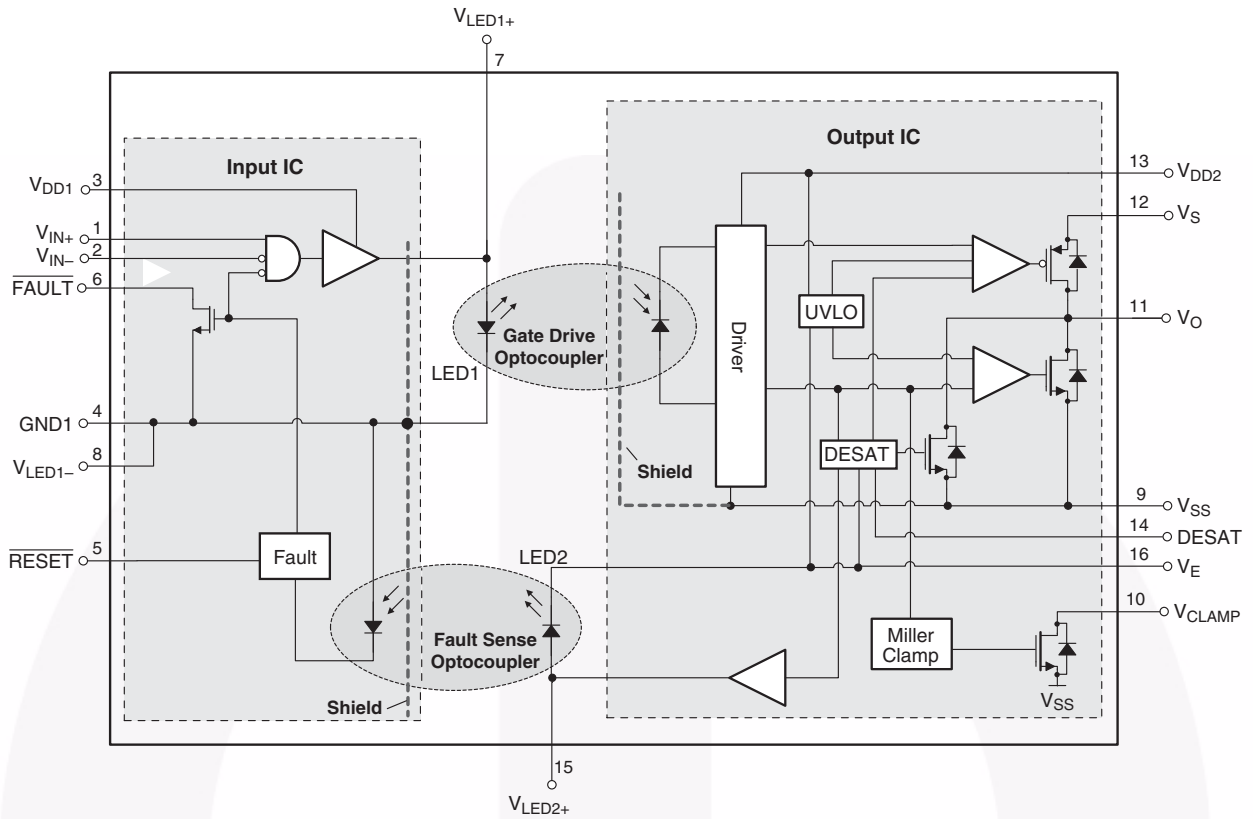

* V_{OUT} is always LOW with 'clamp' being active (gate voltage < 2 V above V_{SS}).

Pin Definitions

Pin #	Name	Description
1	V_{IN+}	Non-inverting gate drive control input
2	V_{IN-}	Inverting gate drive control input
3	V_{DD1}	Positive input supply voltage (3 V to 5.5 V)
4	GND1	Input ground
5	$\overline{\text{RESET}}$	Fault reset input
6	$\overline{\text{FAULT}}$	Fault output
7	V_{LED1+}	LED 1 anode (must be left unconnected)
8	V_{LED1-}	LED 1 cathode (must be connected to ground)
9	V_{SS}	Output supply voltage (negative)
10	V_{CLAMP}	Active Miller clamp supply voltage
11	V_O	Gate drive output voltage
12	V_S	Source of pull-up PMOS transistor
13	V_{DD2}	Positive output supply voltage
14	DESAT	Desaturation voltage input
15	V_{LED2+}	LED 2 anode (must be left unconnected)
16	V_E	Output supply voltage / IGBT emitter

Block Diagram

Safety and Insulation Ratings

As per DIN EN/IEC 60747-5-5. This optocoupler is suitable for “safe electrical insulation” only within the safety limit data. Compliance with the safety ratings shall be ensured by means of protective circuits.

Symbol	Parameter	Min.	Typ.	Max.	Unit
	Installation Classifications per DIN VDE 0110/1.89 Table 1				
	For Rated Mains Voltage < 150 Vrms		I-IV		
	For Rated Mains Voltage < 300 Vrms		I-IV		
	For Rated Mains Voltage < 450 Vrms		I-IV		
	For Rated Mains Voltage < 600 Vrms		I-IV		
	For Rated Mains Voltage < 1000 Vrms		I-III		
	Climatic Classification		40/100/21		
	Pollution Degree (DIN VDE 0110/1.89)		2		
CTI	Comparative Tracking Index	175			
V_{PR}	Input to Output Test Voltage, Method b, $V_{IORM} \times 1.875 = V_{PR}$, 100 % Production Test with $t_m = 1$ s, Partial Discharge < 5 pC	2,651			V_{peak}
	Input to Output Test Voltage, Method a, $V_{IORM} \times 1.5 = V_{PR}$, Type and Sample Test with $t_m = 60$ s, Partial Discharge < 5 pC	2,121			V_{peak}
V_{IORM}	Maximum Working Insulation Voltage	1,414			V_{peak}
V_{IOTM}	Highest Allowable Over Voltage	8,000			V_{peak}
	External Creepage	8			mm
	External Clearance	8			mm
	Insulation Thickness	0.5			mm
T_{Case}	Safety Limit Values – Maximum Values Allowed in the Event of a Failure				
	Case Temperature	150			°C
$P_{S,INPUT}$	Input Power	100			mW
$P_{S,OUTPUT}$	Output Power	600			mW
R_{IO}	Insulation Resistance at T_S , $V_{IO} = 500$ V	10^9			$\frac{3}{4}$

Absolute Maximum Ratings ($T_A = 25\text{ }^\circ\text{C}$ unless otherwise specified)

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Symbol	Parameter	Value	Units
T_{STG}	Storage Temperature	-40 to +125	$^\circ\text{C}$
T_{OPR}	Operating Temperature	-40 to +100	$^\circ\text{C}$
T_J	Junction Temperature	-40 to +125	$^\circ\text{C}$
T_{SOL}	Lead Wave Solder Temperature (no solder immersion) <i>Refer to page 28 for reflow temperature profile.</i>	260 for 10 s	$^\circ\text{C}$
I_{FAULT}	Fault Output Current	15	mA
$I_{O(PEAK)}$	Peak Output Current ⁽¹⁾	3	A
$V_E - V_{SS}$	Negative Output Supply Voltage ⁽²⁾	0 to 15	V
$V_{DD2} - V_E$	Positive Output Supply Voltage	-0.5 to 35 - ($V_E - V_{SS}$)	V
$V_{O(peak)}$	Gate Drive Output Voltage	-0.5 to 35	V
$V_{DD2} - V_{SS}$	Output Supply Voltage	-0.5 to 35	V
V_{DD1}	Positive Input Supply Voltage	-0.5 to 6	V
V_{IN+} , V_{IN-} , and V_{RESET}	Input Voltages	-0.5 to V_{DD1}	V
V_{FAULT}	Fault Pin Voltage	-0.5 to V_{DD1}	V
V_S	Source of Pull-up PMOS Transistor Voltage	$V_{SS} + 6.5$ to V_{DD2}	V
V_{DESAT}	DESAT Voltage	V_E to $V_E + 11$	V
I_{CLAMP}	Peaking Clamping Sinking Current	1.7	A
V_{CLAMP}	Miller Clamping Voltage	-0.5 to V_{DD2}	V
PD_I	Input Power Dissipation ⁽³⁾⁽⁵⁾	100	mW
PD_O	Output Power Dissipation ⁽⁴⁾⁽⁵⁾	600	mW

Notes:

- Maximum pulse width = 10 μs , maximum duty cycle = 0.2 %.
- This negative output supply voltage is optional. It's only needed when negative gate drive is implemented. A schottky diode is recommended to be connected between V_E and V_{SS} to protect against a reverse voltage greater than 0.5 V. Refer to application information, "6. Active Miller Clamp Function" on page 25.
- No derating required across temperature range.
- Derate linearly above 64 $^\circ\text{C}$, free air temperature at a rate of 10.2 mW/ $^\circ\text{C}$
- Functional operation under these conditions is not implied. Permanent damage may occur if the device is subjected to conditions outside these ratings.

Recommended Operating Conditions

The Recommended Operating Conditions table defines the conditions for actual device operation. Recommended operating conditions are specified to ensure optimal performance to the datasheet specifications. Fairchild does not recommend exceeding them or designing to absolute maximum ratings.

Symbol	Parameter	Min.	Max.	Unit
T_A	Ambient Operating Temperature	-40	+100	°C
V_{DD1}	Input Supply Voltage ⁽⁶⁾	3	5.5	V
$V_{DD2} - V_{SS}$	Total Output Supply Voltage	15	30	V
$V_E - V_{SS}$	Negative Output Supply Voltage	0	15	V
$V_{DD2} - V_E$	Positive Output Supply Voltage ⁽⁶⁾	15	$30 - (V_E - V_{SS})$	V
V_S	Source of Pull-up PMOS Transistor Voltage	$V_{SS} + 7.5$	V_{DD2}	V

Note:

6. During power up or down, it is important to ensure that VIN+ remains LOW until both the input and output supply voltages reach the proper recommended operating voltage to avoid any momentary instability at the output state. Refer to "Time to Good Power" section on page 25.

Isolation Characteristics

Apply over all recommended conditions, typical value is measured at $T_A = 25\text{ °C}$

Symbol	Parameter	Conditions	Min.	Typ.	Max.	Units
V_{ISO}	Input-Output Isolation Voltage	$T_A = 25\text{ °C}$, R.H. < 50 %, $t = 1.0\text{ min}$, $I_{I-O} \delta 10\text{ }\mu\text{A}$, 50 Hz ⁽⁷⁾⁽⁸⁾⁽⁹⁾	4,243			V_{RMS}
R_{ISO}	Isolation Resistance	$V_{I-O} = 500\text{ V}^{(7)}$		10^{11}		Ω
C_{ISO}	Isolation Capacitance	$V_{I-O} = 0\text{ V}$, freq = 1.0 MHz ⁽⁷⁾		1		pF

Notes:

7. Device is considered a two terminal device: pins 1 to 8 are shorted together and pins 9 to 16 are shorted together.
 8. 4,243 V_{RMS} for 1-minute duration is equivalent to 5,091 V_{RMS} for 1-second duration.
 9. The Input-Output Isolation Voltage is a dielectric voltage rating as per UL1577. It should not be regarded as an input-output continuous voltage rating. For the continuous working voltage rating, refer to the equipment level safety specification or *DIN EN/IEC 60747-5-5 Safety and Insulation Ratings Table* on page 4.

Electrical Characteristics

Apply over all recommended conditions; typical value is measured at $V_{DD1} = 5\text{ V}$, $V_{DD2} - V_{SS} = 30\text{ V}$, $V_E - V_{SS} = 0\text{ V}$, $T_A = 25\text{ °C}$ unless otherwise specified.

V_{DESAT}	DESAT Threshold ⁽¹⁴⁾	$V_{DD2} - V_E > V_{UVLO-}$, $V_O < 5\text{ V}$	6	7	9	V	16, 41
V_{CLAMP_THRES}	Clamping Threshold Voltage			2.2		V	33, 52
I_{CLAMPL}	Clamp Low Level Sinking Current	$V_O = V_{SS} + 2.5\text{ V}$	0.35	1.2		A	32, 51

Notes:

- Maximum pulse width = $10\text{ }\mu\text{s}$, maximum duty cycle = 0.2 %.
- Maximum pulse width = 4.99 ms, maximum duty cycle = 99.8 %.
- V_{OH} is measured with the DC load current in this testing (maximum pulse width = 1 ms, maximum duty cycle = 20 %). When driving capacitive loads, V_{OH} approaches V_{DD} as I_{OH} approaches zero units.
- Positive output supply voltage ($V_{DD2} - V_E$) should be at least 15 V. This ensures adequate margin in excess of the maximum under-voltage lockout threshold V_{UVLO+} of 13.5 V.
- When $V_{DD2} - V_E > V_{UVLO}$ and output state V_O of the FOD8318 is allowed to go HIGH, the DESAT detection feature is active and provides the primary source of IGBT protection. UVLO is needed to ensure DESAT detection is functional.
- The blanking time, t_{BLANK} , is adjustable by an external capacitor (C_{BLANK}) where $t_{BLANK} = C_{BLANK} * (V_{DESAT} / I_{CHG})$.

Switching Characteristics

Apply over all recommended conditions; typical value is measured at $V_{DD1} = 5\text{ V}$, $V_{DD2} - V_{SS} = 30\text{ V}$, $V_E - V_{SS} = 0\text{ V}$, $T_A = 25\text{ }^\circ\text{C}$ unless otherwise specified.

Notes:

16. This load condition approximates the gate load of a 1200 V / 150 A IGBT.
17. t_{PHL} propagation delay is measured from the 50 % level on the falling edge of the input pulse (V_{IN+} , V_{IN-}) to the 50 % level of the falling edge of the V_O signal. Refer to Figure 53.
18. t_{PLH} propagation delay is measured from the 50 % level on the rising edge of the input pulse (V_{IN+} , V_{IN-}) to the 50 % level of the rising edge of the V_O signal. Refer to Figure 53.
19. PWD is defined as $|t_{PHL} - t_{PLH}|$ for any given device.
20. The difference between t_{PHL} and t_{PLH} between any two FOD8318 parts under same operating conditions, with equal loads.
21. This is the amount of time the DESAT threshold must be exceeded before V_O begins to go LOW. This is supply voltage dependent. Refer to Figure 54.

22. This is the amount of time from when the DESAT threshold is exceeded, until the $\overline{\text{FAULT}}$ output goes LOW. Refer to Figure 54.
23. This is the amount of time the DESAT threshold must be exceeded before V_O begins to go LOW and the $\overline{\text{FAULT}}$ output to go LOW. Refer to Figure 54.
24. This is the amount of time from when $\overline{\text{RESET}}$ is asserted LOW, until $\overline{\text{FAULT}}$ output goes HIGH. Refer to Figure 54.
25. $t_{\text{UVLO ON}}$ UVLO turn-on delay is measured from $V_{\text{UVLO+}}$ threshold voltage of the output supply voltage (V_{DD2}) to the 5 V level of the rising edge of the V_O signal.
26. $t_{\text{UVLO OFF}}$ UVLO turn-off delay is measured from $V_{\text{UVLO-}}$ threshold voltage of the output supply voltage (V_{DD2}) to the 5 V level of the falling edge of the V_O signal.
27. t_{GP} time to good power is measured from 13.5 V level of the rising edge of the output supply voltage (V_{DD2}) to the 5 V level of the rising edge of the V_O signal.
28. Common mode transient immunity at output HIGH state is the maximum tolerable negative dV_{cm}/dt on the trailing edge of the common mode pulse, V_{CM} , to assure that the output remains in HIGH state (i.e., $V_O > 15 \text{ V}$ or $\overline{\text{FAULT}} > 2 \text{ V}$).
29. Common mode transient immunity at output LOW state is the maximum positive tolerable dV_{cm}/dt on the leading edge of the common mode pulse, V_{CM} , to assure that the output remains in a LOW state (i.e., $V_O < 1.0 \text{ V}$ or $\overline{\text{FAULT}} < 0.8 \text{ V}$).

Functional Description

The functional behavioral of FOD8318 is illustrated by the detailed internal schematic shown in Figure 56. This explains the interaction and sequence of internal and external signals, together with the timing diagrams.

1. Non-Inverting and Inverting Inputs

There are two CMOS/TTL-compatible inputs, V_{IN+} and V_{IN-}, to control the IGBT in non-inverting and inverting configurations, respectively. When V_{IN-} is set to LOW state, V_{IN+} controls the driver output, V_O, in non-inverting configuration. When V_{IN+} is set to HIGH state, V_{IN-} controls the driver output in inverting configuration.

The relationship between the inputs and output are illustrated in the Figure 57.

During normal operation, when no fault is detected, the FAULT output, which is an open-drain configuration, is latched to HIGH state. This allows the gate driver to be controlled by the input logic signal.

When a fault is detected, the FAULT output is latched to LOW state. This condition remains until the input logic is pulled to LOW and the RESET pin is also pulled LOW for a period longer than PW_{RESET}.

Figure 56. Detailed Internal Schematic

2. Gate Driver Output

A pair of PMOS and NMOS comprise the output driver stage, which facilitates close to rail-to-rail output swing. This feature allows a tight control of gate voltage during on-state and short-circuit condition. The output driver is typically to sink 2 A and source 2 A at room temperature. Due to the low $R_{DS(ON)}$ of the MOSFETs, the power dissipation is reduced as compared to those bipolar-type driver output stages. The absolute maximum rating of the output peak current, $I_{O(PEAK)}$, is 3 A; therefore the careful selection of the gate resistor, R_g , is required to limit the short-circuit current of the IGBT.

As shown in Figure 56, gate driver output is influenced by signals from the photodetector circuitry, the UVLO comparator, and the DESAT signals. Under no-fault condition, normal operation resumes while the supply voltage is above the UVLO threshold, the output of the photodetector drives the MOSFETs of the output stage.

The logic circuitry of the output stage ensures that the push-pull devices are never “ON” simultaneously. When the output of the photodetector is HIGH, the output, V_O , is pulled to HIGH state by turning on the PMOS. When the output of the photodetector is LOW, V_O is pulled to LOW state by turning on the NMOS.

When V_{DD2} supply goes below V_{UVLO} , which is the designated UVLO threshold at the comparator, V_O is pulled down to LOW state regardless of photodetector output.

When desaturation is detected, V_O turns off slowly as it is pulled LOW by the NMOS^{1X} device. The input to the fault sense circuitry is latched to HIGH state and turns on the LED. When V_O goes below 2 V, the NMOS^{50X} device turns on again, clamping the IGBT gate firmly to V_{SS} . The Fault Sense signal remains latched in the HIGH state until the LED of the gate driver circuitry turns off.

3. Desaturation Protection, FAULT Output

Desaturation detection protection ensures the protection of the IGBT at short-circuit by monitoring the collector-emitter voltage of the IGBT in the half bridge. When the DESAT voltage goes up and reaches above the threshold voltage, a short-circuit condition is detected and the driver output stage executes a “soft” IGBT turn-off and is eventually driven LOW, as illustrated in Figure 58. The FAULT open-drain output is triggered active LOW to report a desaturation error. It is only cleared by activating active LOW by the external controller to the RESET input with the input logic is pulled to LOW.

The DESAT fault detector should be disabled for a short period (blanking time) before the IGBT turns on to allow the collector voltage to fall below DESAT threshold. This blanking period protects against false trigger of the DESAT while the IGBT is turning on.

The blanking time is controlled by the internal DESAT charge current, the DESAT voltage threshold, and the external DESAT capacitor (capacitor between DESAT and V_E pin). The nominal blanking time can be calculated using external capacitance (C_{BLANK}), FAULT

threshold voltage (V_{DESAT}), and DESAT charge current (I_{CHG}) as:

$$t_{BLANK} = C_{BLANK} \times V_{DESAT} / I_{CHG}$$

With a recommended 100 pF DESAT capacitor, the nominal blanking time is:

$$100 \text{ pF} \times 7 \text{ V} / 250 \text{ } \mu\text{A} = 2.8 \text{ } \mu\text{s}$$

4. “Soft” Turn-Off

The soft turn-off feature ensures the safe turn off of the IGBT under fault conditions. This reduces the voltage spike on the collector of the IGBT. Without this, the IGBT would see a heavy spike on the collector and result in permanent damage to the device.

5. Under-Voltage Lockout

Under-voltage detection prevents the application of insufficient gate voltage to the IGBT. This could be dangerous, as it would drive the IGBT out of saturation and into the linear operation where the losses are very high and quickly overheated. This feature ensures the proper operating of the IGBTs. The output voltage, V_O , remains LOW regardless of the inputs as long as the supply voltage, $V_{DD2} - V_E$, is less than V_{UVLO+} . When the supply voltage falls below V_{UVLO-} , V_O goes LOW, as illustrated in Figure 59.

6. Active Miller Clamp Function

An active Miller clamp feature allows the sinking of the Miller current to the ground or emitter of the IGBT during a high-dV/dt situation. Instead of driving the IGBT gate to a negative supply voltage to increase the safety margin, the device has a dedicated V_{CLAMP} pin to control the Miller current. During turn-off, the gate voltage of the IGBT is monitored and the V_{CLAMP} output is activated when the gate voltage goes below 2 V (relative to V_{SS}). The Miller clamp NMOS transistor is then turned on and provides a low resistive path for the Miller current. This helps prevent a self-turn-on due to the parasitic Miller capacitor in power switches. The clamp voltage is $V_{OL} + 2.5 \text{ V}$ maximum for a Miller current up to 1200 mA. In this way, the V_{CLAMP} function does not affect the turn-off characteristic. It helps to clamp the gate to the LOW level throughout the turn-off time. During turn-on, where the input of the driver is activated, the V_{CLAMP} function is disabled or opened.

7. Time to Good Power

At initial power up, the LED is off and the output of the gate driver should be in the LOW state. Sometimes race conditions exist that causes the output to follow the V_E (assuming V_{DD2} and V_E are connected externally), until all of the circuits in the output IC have stabilized. This condition can result in output transitions or transients that are coupled to the driven IGBT. These glitches can cause the high-side and low-side IGBTs to conduct shoot-through current that may result in destructive damage to the power semiconductor devices. Fairchild has introduced a initial turn-on delay, generally called “time-to-good power”. This delay, typically 30 μs , is only

present during the initial power-up of the device. Once powered, the “time-to-good power” delay is determined by the delay of the UVLO circuitry. If the LED is “ON”

during the initial turn-on activation, LOW-to-HIGH transition at the output of the gate driver only occurs 30 μ s after the V_{DD2} power is applied.
