## 1-Gbit, 2112-byte/1056-word page,

1.8 V/3 V, single level cell NAND flash memory

## Features

- NAND interface
- x8 or x16 bus width
- Multiplexed address/ data
- Pinout compatibility for all densities

■ Supply voltage: 1.8 V/3 V

- Page size
- x8 device: (2048 + 64 spare) bytes
- x16 device: (1024 + 32 spare) words
- Block size
- x8 device: (128K + 4K spare) bytes
- x16 device: ( $64 \mathrm{~K}+2 \mathrm{~K}$ spare) words
- Page read/program
- Random access: 25 us (max)
- Sequential access: 25 ns (min)
- Page program time: $200 \mu \mathrm{~s}$ (typ)
- Copy back program mode
- Cache read mode
- Fast block erase: 2 ms (typ)
- Status register
- Electronic signature
- Chip enable 'don’t care'
- Security features
- OTP area
- Serial number (unique ID)
- Non-volatile protection option
- Data protection
- Hardware block locking

TSOP48 $12 \times 20 \mathrm{~mm}$

VFBGA63 $9 \times 11 \times 1.05 \mathrm{~mm}$ VFBGA153 $8 \times 9 \times 0.9 \mathrm{~mm}$

- Hardware program/erase locked during power transitions
■ ONFI 1.0 support
- Cache read
- Read signature
- Read
- Data integrity
- 100,000 program/erase cycles per block (with ECC)
- 10 years data retention

■ RoHS compliant packages
■ Development tools

- Error correction code models
- Bad blocks management and wear leveling algorithms
- Hardware simulation models

## 1 Description

The NAND01G-B2C is a 1 -Gbit device belonging to the NAND SLC large page family. The device operates with a 1.8 V or 3 V voltage supply. The size of a page is either 2112 bytes ( $2048+64$ spare) or 1056 words ( $1024+32$ spare) depending on whether the device has a x8 or x16 bus width.

The address lines are multiplexed with the data input/output signals on a multiplexed $x 8$ or x16 input/output bus. This interface reduces the pin count and makes it possible to migrate to other densities without changing the footprint.

Each block can be programmed and erased up to 100,000 cycles (with ECC on). To extend the lifetime of NAND flash devices, the implementation of an error correction code (ECC) is mandatory.

The devices feature a write protect pin that allows performing hardware protection against program and erase operations.
The devices feature an open-drain ready/busy output that can be used to identify if the program/erase/read (P/E/R) controller is currently active. The use of an open-drain output allows the ready/busy pins from several memories to be connected to a single pull-up resistor.

A Copy Back Program command is available to optimize the management of defective blocks. When a page program operation fails, the data can be programmed in another page without having to resend the data to be programmed.

The cache read feature is also implemented according to ONFI 1.0 specification.
All devices have the chip enable don't care feature, which allows the bus to be shared among several memories active at the same time, as chip enable transitions during the latency time do not stop the read operation. Program and erase operations can never be interrupted by chip enable transitions.

The devices are available in the following packages:

- TSOP48 (12 x 20 mm )
- VFBGA63 ( $9 \times 11 \times 1.05 \mathrm{~mm}, 0.8 \mathrm{~mm}$ pitch)
- VFBGA153 (8 x $9 \times 0.9 \mathrm{~mm}, 0.5 \mathrm{~mm}$ pitch)
and come with three security features:
- OTP (one time programmable) area, which is a restricted access area where sensitive data/code can be stored permanently.
- Serial number (unique identifier), which allows the devices to be uniquely identified.
- Non-volatile protection to lock sensible data permanently. For more details of this option contact your nearest Numonyx sales office.

These security features are subject to an NDA (non-disclosure agreement) and are, therefore, not described in the datasheet. For more details about them, refer to the nearest Numonyx sales office.

For information on how to order these options refer to Table 28: Ordering information scheme. Devices are shipped from the factory with block 0 always valid and the memory content bits, in valid blocks, erased to '1'.

See Table 2: Product description, for all the devices available in the family.

## 2 Memory array organization

The memory array is made up of two NAND structures where 32 cells are connected in series.
The memory array is organized in blocks where each block contains 64 pages. The array is split into two areas, the main area and the spare area. The main area of the array is used to store data whereas the spare area is typically used to store error correction codes, software flags or bad block identification.
In $\times 8$ devices the pages are split into a 2048 -byte main area and a spare area of 64 bytes. In the x 16 devices the pages are split into a 1024 -word main area and a 32 -word spare area. Refer to Figure 6: Memory array organization.

### 2.1 Bad blocks

The NAND flash 2112-byte/1056-word page devices may contain bad blocks, that is blocks that contain one or more invalid bits whose reliability is not guaranteed. Additional bad blocks may develop during the lifetime of the device.
The bad block Information is written prior to shipping (refer to Section 8.1: Bad block management for more details).
Table 4: Valid blocks shows the minimum number of valid blocks in the device. The values shown include both the bad blocks that are present when the device is shipped and the bad blocks that could develop later on.
These blocks need to be managed using bad blocks management, block replacement or error correction codes (refer to Section 8: Software algorithms).

Table 4. Valid blocks

| Density of device | Min | Max |
| :---: | :---: | :---: |
| 1 Gbit | 1004 | 1024 |

Figure 6. Memory array organization

## 3 Signal descriptions

See Figure 2: Logic diagram, and Table 3: Signal names, for a brief overview of the signals connected to this device.

### 3.1 Inputs/outputs (I/O0-I/O7)

Input/outputs 0 to 7 are used to input the selected address, output the data during a read operation or input a command or data during a write operation. The inputs are latched on the rising edge of Write Enable. I/O0-l/O7 are left floating when the device is deselected or the outputs are disabled.

### 3.2 Inputs/outputs (I/O8-I/O15)

Input/outputs 8 to 15 are only available in $\times 16$ devices. They are used to output the data during a read operation or input data during a write operation. Command and address inputs only require I/O0 to I/O7.

The inputs are latched on the rising edge of Write Enable. I/O8-I/O15 are left floating when the device is deselected or the outputs are disabled.

### 3.3 Address Latch Enable (AL)

The Address Latch Enable activates the latching of the address inputs in the command interface. When AL is High, the inputs are latched on the rising edge of Write Enable.

### 3.4 Command Latch Enable (CL)

The Command Latch Enable activates the latching of the command inputs in the command interface. When CL is High, the inputs are latched on the rising edge of Write Enable.

### 3.5 Chip Enable ( $\overline{\mathrm{E}}$ )

The Chip Enable input activates the memory control logic, input buffers, decoders and sense amplifiers. When Chip Enable is Low, $\mathrm{V}_{\mathrm{IL}}$, the device is selected. If Chip Enable goes High, $\mathrm{V}_{\mathrm{IH}}$, while the device is busy, the device remains selected and does not go into standby mode.

### 3.6 Read Enable ( $\overline{\mathbf{R}}$ )

The Read Enable pin, $\overline{\mathrm{R}}$, controls the sequential data output during read operations. Data is valid $t_{R L Q V}$ after the falling edge of $\bar{R}$. The falling edge of $\bar{R}$ also increments the internal column address counter by one.

### 3.7 Write Enable ( $\overline{\mathrm{W}}$ )

The Write Enable input, $\overline{\mathrm{W}}$, controls writing to the command interface, input address and data latches. Both addresses and data are latched on the rising edge of Write Enable.
During power-up and power-down a recovery time of $10 \mu \mathrm{~s}(\mathrm{~min})$ is required before the command interface is ready to accept a command. It is recommended to keep Write Enable High during the recovery time.

### 3.8 Write Protect ( $\overline{\mathrm{WP}}$ )

The Write Protect pin is an input that gives a hardware protection against unwanted program or erase operations. When Write Protect is Low, $\mathrm{V}_{\mathrm{IL}}$, the device does not accept any program or erase operations.

It is recommended to keep the Write Protect pin Low, $\mathrm{V}_{\mathrm{IL}}$, during power-up and power-down.

### 3.9 Ready/Busy ( $\mathbf{R} \overline{\mathbf{B}}$ )

The Ready/Busy output, $R \overline{\mathrm{~B}}$, is an open-drain output that can be used to identify if the $P / E / R$ controller is currently active. When Ready/Busy is Low, $\mathrm{V}_{\mathrm{OL}}$, a read, program or erase operation is in progress. When the operation completes Ready/Busy goes High, $\mathrm{V}_{\mathrm{OH}}$.
The use of an open-drain output allows the Ready/Busy pins from several memories to be connected to a single pull-up resistor. A Low will then indicate that one, or more, of the memories is busy.
Refer to the Section 11.1: Ready/Busy signal electrical characteristics for details on how to calculate the value of the pull-up resistor.

During power-up and power-down a minimum recovery time of $10 \mu \mathrm{~s}$ is required before the command interface is ready to accept a command. During this period the $\mathrm{R} \overline{\mathrm{B}}$ signal is Low, $\mathrm{V}_{\mathrm{OL}}$.

## $3.10 \quad V_{D D}$ supply voltage

$V_{D D}$ provides the power supply to the internal core of the memory device. It is the main power supply for all operations (read, program and erase).
An internal voltage detector disables all functions whenever $\mathrm{V}_{\mathrm{DD}}$ is below $\mathrm{V}_{\text {LKO }}$ (see Table 22 and Table 23) to protect the device from any involuntary program/erase during power-transitions.
Each device in a system should have $\mathrm{V}_{\mathrm{DD}}$ decoupled with a $0.1 \mu \mathrm{~F}$ capacitor. The PCB track widths should be sufficient to carry the required program and erase currents.

## $3.11 \quad V_{\text {SS }}$ ground

Ground, $\mathrm{V}_{\mathrm{SS}}$, is the reference for the power supply. It must be connected to the system ground.

## 4 Bus operations

There are six standard bus operations that control the memory. Each of these is described in this section, see Table 5: Bus operations, for a summary.
Typically, glitches of less than 5 ns on Chip Enable, Write Enable and Read Enable are ignored by the memory and do not affect bus operations.

### 4.1 Command input

Command input bus operations are used to give commands to the memory. Commands are accepted when Chip Enable is Low, Command Latch Enable is High, Address Latch Enable is Low and Read Enable is High. They are latched on the rising edge of the Write Enable signal. For commands that start a modify operation (write/erase) the Write Protect pin must be High.

Only I/O0 to I/O7 are used to input commands.
See Figure 21 and Table 24 for details of the timings requirements.

### 4.2 Address input

Address input bus operations are used to input the memory addresses. Four bus cycles are required to input the addresses for 1-Gbit devices (refer to Table 6 and Table 7, Address insertion).
The addresses are accepted when Chip Enable is Low, Address Latch Enable is High, Command Latch Enable is Low and Read Enable is High. They are latched on the rising edge of the Write Enable signal. For commands that start a modify operation (write/erase) the Write Protect pin must be High. Only I/O0 to I/O7 are used to input addresses.
See Figure 22 and Table 24 for details of the timings requirements.

### 4.3 Data input

Data input bus operations are used to input the data to be programmed.
Data is accepted only when Chip Enable is Low, Address Latch Enable is Low, Command Latch Enable is Low, Read Enable, and Write Protect is High. The data is latched on the rising edge of the Write Enable signal. The data is input sequentially using the Write Enable signal.
See Figure 23 and Table 24 and Table 25 for details of the timings requirements.

### 4.4 Data output

Data output bus operations are used to read: the data in the memory array, the status register, the electronic signature and the unique identifier.

Data is output when Chip Enable is Low, Write Enable is High, Address Latch Enable is Low, and Command Latch Enable is Low. The data is output sequentially using the Read Enable signal.

See Figure 24 and Table 25 for details of the timings requirements.

### 4.5 Write Protect

Write Protect bus operations are used to protect the memory against program or erase operations. When the Write Protect signal is Low the device will not accept program or erase operations and so the contents of the memory array cannot be altered. The Write Protect signal is not latched by Write Enable to ensure protection even during power-up.

### 4.6 Standby

When Chip Enable is High the memory enters standby mode, the device is deselected, outputs are disabled and power consumption is reduced.

Table 5. Bus operations

| Bus operation | $\overline{\mathbf{E}}$ | $\mathbf{A L}$ | $\mathbf{C L}$ | $\overline{\mathbf{R}}$ | $\overline{\mathrm{W}}$ | $\overline{\mathrm{WP}}$ | $\mathbf{I / O 0} \mathbf{- I / O 7}$ | $\mathbf{I / 0 8} \mathbf{- I / O 1 5}{ }^{(\mathbf{1})}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Command input | $\mathrm{V}_{\mathrm{IL}}$ | $\mathrm{V}_{\mathrm{IL}}$ | $\mathrm{V}_{\mathrm{IH}}$ | $\mathrm{V}_{\mathrm{IH}}$ | Rising | $\mathrm{X}^{(2)}$ | Command | X |
| Address input | $\mathrm{V}_{\mathrm{IL}}$ | $\mathrm{V}_{\mathrm{IH}}$ | $\mathrm{V}_{\mathrm{IL}}$ | $\mathrm{V}_{\mathrm{IH}}$ | Rising | X | Address | X |
| Data input | $\mathrm{V}_{\mathrm{IL}}$ | $\mathrm{V}_{\mathrm{IL}}$ | $\mathrm{V}_{\mathrm{IL}}$ | $\mathrm{V}_{\mathrm{IH}}$ | Rising | $\mathrm{V}_{\mathrm{IH}}$ | Data input | Data input |
| Data output | $\mathrm{V}_{\mathrm{IL}}$ | $\mathrm{V}_{\mathrm{IL}}$ | $\mathrm{V}_{\mathrm{IL}}$ | Falling | $\mathrm{V}_{\mathrm{IH}}$ | X | Data output | Data output |
| Write Protect | X | X | X | X | X | $\mathrm{V}_{\mathrm{IL}}$ | X | X |
| Standby | $\mathrm{V}_{\mathrm{IH}}$ | X | X | X | X | $\mathrm{V}_{\mathrm{IL}} / \mathrm{V}_{\mathrm{D}}$ | X | D |

1. Only for x 16 devices.
2. $\overline{\mathrm{WP}}$ must be $\mathrm{V}_{\mathrm{IH}}$ when issuing a program or erase command.

## 5 Command set

All bus write operations to the device are interpreted by the command interface. The commands are input on I/O0-I/O7 and are latched on the rising edge of Write Enable when the Command Latch Enable signal is High. Device operations are selected by writing specific commands to the command register. The two-step command sequences for program and erase operations are imposed to maximize data security.

The commands are summarized in Table 10: Commands.
Table 10. Commands

| Command | Bus write operations $^{(1)}$ |  |  |  | Commands <br> accepted <br> during <br> busy |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{1}^{\text {st }}$ cycle | $\mathbf{2}^{\text {nd }}$ cycle | $3^{\text {rd }}$ cycle | $\mathbf{4}^{\text {th }}$ cycle | ( |
| Read | 00 h | 30 h | - | - |  |
| Random Data Output | 05 h | E0h | - | - |  |
| Cache Read | 00 h | 31 h | - | - |  |
| Exit Cache Read | $3 F \mathrm{~h}$ | - | - | - |  |
| Page Program <br> (sequential input default) | 80 h | 10 h | - | - |  |
| Random Data Input | 85 h | - | - | - |  |
| Copy Back Program | 00 h | 35 h | 85 h | 10 h |  |
| Block Erase | 60 h | D0h | - | - |  |
| Reset | FFh | - | - | - | Yes |
| Read Electronic Signature | 90 h | - | - | - |  |
| Read Status Register | 70 h | - | - | - | Yes |
| Read ONFI Parameter Page | ECh | - | - | - |  |

1. The bus cycles are only shown for issuing the codes. The cycles required to input the addresses or input/output data are not shown.

## 6 Device operations

The following section gives the details of the device operations.

### 6.1 Read memory array

At power-up the device defaults to read mode. To enter read mode from another mode the Read command must be issued, see Table 10: Commands.
Once a Read command is issued two types of operations are available: random read and page read.

### 6.1.1 Random read

Each time the Read command is issued the first read is random read.

### 6.1.2 Page read

After the first random read access, the page data ( 2112 bytes or 1056 words) is transferred to the page buffer in a time of $t_{\text {WHBH }}$ (refer to Table 25 for value). Once the transfer is complete the Ready/Busy signal goes High. The data can then be read out sequentially (from selected column address to last column address) by pulsing the Read Enable signal.

Alternatively, the user may check the transfer completion by issuing the Read Status Register command and checking SR6 by toggling $\bar{R}$. In the latter case, the device will keep on outputting the read status register until the 00h command is issued.

The device can output random data in a page, instead of the consecutive sequential data, by issuing a Random Data Output command.

The Random Data Output command can be used to skip some data during a sequential data output.

The sequential operation can be resumed by changing the column address of the next data to be output, to the address which follows the Random Data Output command.

The Random Data Output command can be issued as many times as required within a page.

The Random Data Output command is not accepted during cache read operations.

Figure 7. Read operations

Figure 8. Read operations (intercepted by $\overline{\text { E }}$ )

Figure 9. Random data output during sequential data output

### 6.2 Cache read

The cache read operation is used to improve the read throughput by reading data using the cache register. Since the device has only one cache register, serial data output on one page may be executed while data from another page is read into the cache register.

A Page Read command must be issued prior to the Sequential or Random Cache Read command in a cache read sequence. The Cache Read command can be issued only after the read function is complete (SR6 $=$ ' 1 ').

A cache read operation consists of three steps (see Table 10: Commands):

1. One bus cycle is required to setup the Cache Read command (the same as the standard Read command)
2. Four (refer to Table 6 and Table 7) bus cycles are then required to input the start address. If the host does not enter an address, the next sequential page is read.
3. One bus cycle is required to issue the Cache Read Confirm command to start the P/E/R controller.

The start address must be at the beginning of a page (column address $=00 \mathrm{~h}$, see Table 8 and Table 9). This allows the data to be output uninterrupted after the latency time ( $\mathrm{t}_{\mathrm{BLBH} 1}$ ), see Figure 10.
The Ready/Busy signal can be used to monitor the start of the operation. During the latency period the Ready/Busy signal goes Low, after this the Ready/Busy signal goes High, even if the device is internally downloading page $\mathrm{n}+1$.

Once the cache read operation has started, the status register can be read using the Read Status Register command.
During the operation, SR5 can be read, to find out whether the internal reading is ongoing (SR5 = ' 0 '), or has completed (SR5 = ' 1 '), while SR6 indicates whether the cache register is ready to download new data.

To exit the cache read operation an Exit Cache Read command must be issued (see Table 10).

After the device has internally read page $n$, the user is allowed to download data of that page by toggling $\bar{R}$, but the device will not trigger internally the reading of a next page.

Figure 10. Cache read operation

### 6.3 Page program

The page program operation is the standard operation to program data to the memory array. Within a given block, the pages must be programmed sequentially. Random page address programming is not recommended.

The memory array is programmed by page, however partial page programming is allowed where any number of bytes ( 1 to 2112) or words ( 1 to 1056) can be programmed.
The maximum number of consecutive partial page program operations allowed in the same page is four. After exceeding this a Block Erase command must be issued before any further program operations can take place in that page.

### 6.3.1 Sequential input

To input data sequentially the addresses must be sequential and remain in one block.
For sequential input each page program operation consists of five steps (see Figure 11):

1. one bus cycle is required to setup the Page Program (sequential input) command (see Table 10)
2. four bus cycles are then required to input the program address (refer to Table 6 and Table 7)
3. the data is then loaded into the data registers
4. one bus cycle is required to issue the Page Program Confirm command to start the $P / E / R$ controller. The P/E/R will only start if the data has been loaded in step 3
5. the $P / E / R$ controller then programs the data into the array.

### 6.3.2 Random data input in a page

During a sequential input operation, the next sequential address to be programmed can be replaced by a random address, by issuing a Random Data Input command. The following two steps are required to issue the command:

1. one bus cycle is required to setup the Random Data Input command (see Table 10)
2. two bus cycles are then required to input the new column address (refer to Table 6).

Random Data Input can be repeated as often as required in any given page.
Once the program operation has started the status register can be read using the Read Status Register command. During program operations the status register will only flag errors for bits set to ' 1 ' that have not been successfully programmed to '0'.

During the program operation, only the Read Status Register and Reset commands will be accepted, all other commands will be ignored.
Once the program operation has completed the P/E/R controller bit SR6 is set to ' 1 ' and the Ready/Busy signal goes High.

The device remains in read status register mode until another valid command is written to the command interface.

Figure 11. Page program operation

Figure 12. Random data input during sequential data input

### 6.4 Copy back program

The copy back program operation is used to copy the data stored in one page and reprogram it in another page.

The copy back program operation does not require external memory and so the operation is faster and more efficient because the reading and loading cycles are not required. The operation is particularly useful when a portion of a block is updated and the rest of the block needs to be copied to the newly assigned block.

If the copy back program operation fails, an error is signalled by the pass/fail status. However, if copy back operations are accumulated over time, a bit error due to charge loss is not checked by an external error detection/correction scheme. For this reason it is recommended to use a 2-bit error correction in a copy back operation.

The copy back program operation requires four steps:

1. The first step reads the source page. The operation copies all 1056 words/ 2112 bytes from the page into the data buffer. It requires:

- one bus write cycle to setup the command
- 4 bus write cycles to input the source page address (see Table 6 and Table 7)
- one bus write cycle to issue the confirm command code

2. When the device returns to the ready state (Ready/Busy High), the user may read the contents of the source page by toggling $\overline{\mathrm{R}}$. In this case, random data output is also allowed. To proceed with the copy back of the page into the target location, the user will issue 85 h followed by 4 bus cycles to input the target page address (see Table 6 and Table 7).
3. Then the confirm command is issued to start the $P / E / R$ controller.

For an example of the copy back program operation, refer to Figure 13, while Figure 14 shows an example of Copy Back Program with Random Data Input.
A data input cycle to modify a portion or a multiple distant portion of the source page, is shown in Figure 14.

Figure 13. Copy back program

Figure 14. Page copy back program with random data input

### 6.5 Block erase

Erase operations are done one block at a time. An erase operation sets all of the bits in the addressed block to ' 1 '. All previous data in the block is lost.
An erase operation consists of three steps (refer to Figure 15):

1. One bus cycle is required to setup the Block Erase command. Only addresses A18A27 (x8) or A17-A26 (x16) are used, the other address inputs are ignored
2. Two bus cycles are then required to load the address of the block to be erased. Refer to Table 8 and Table 9 for the block addresses of each device
3. One bus cycle is required to issue the Block Erase Confirm command to start the P/E/R controller.
The operation is initiated on the rising edge of write Enable, $\bar{W}$, after the Confirm command is issued. The P/E/R controller handles block erase and implements the verify process.
During the block erase operation, only the Read Status Register and Reset commands will be accepted, all other commands will be ignored.
Once the program operation has completed the P/E/R controller bit SR6 is set to ' 1 ' and the Ready/Busy signal goes High. If the operation completed successfully, the write status bit SR0 is ' 0 ', otherwise it is set to ' 1 '.

Figure 15. Block erase operation

### 6.6 Reset

The Reset command is used to reset the command interface and status register. If the Reset command is issued during any operation, the operation will be aborted. If it was a program or erase operation that was aborted, the contents of the memory locations being modified will no longer be valid as the data will be partially programmed or erased.
If the device has already been reset then the new Reset command will not be accepted.
The Ready/Busy signal goes Low for $t_{B L B H 4}$ after the Reset command is issued. The value of $t_{B L B H 4}$ depends on the operation that the device was performing when the command was issued, refer to Table 25: AC characteristics for operations for the values.

### 6.7 Read status register

The device contains a status register which provides information on the current or previous program or erase operation. The various bits in the status register convey information and errors on the operation.

The status register is read by issuing the Read Status Register command. The status register information is present on the output data bus (I/O0-l/O7) on the falling edge of Chip Enable or Read Enable, whichever occurs last. When several memories are connected in a system, the use of Chip Enable and Read Enable signals allows the system to poll each device separately, even when the Ready/Busy pins are common-wired. It is not necessary to toggle the Chip Enable or Read Enable signals to update the contents of the status register.

After the Read Status Register command has been issued, the device remains in read status register mode until another command is issued. Therefore if a Read Status Register command is issued during a random read cycle a new Read command must be issued to continue with a page read operation.

The Status Register bits are summarized in Table 11: Status register bits,. Refer to Table 11 in conjunction with the following text descriptions.

### 6.7.1 Write protection bit (SR7)

The write protection bit can be used to identify if the device is protected or not. If the write protection bit is set to ' 1 ' the device is not protected and program or erase operations are allowed. If the write protection bit is set to ' 0 ' the device is protected and program or erase operations are not allowed.

### 6.7.2 P/E/R controller and cache ready/busy bit (SR6)

Status register bit SR6 has two different functions depending on the current operation.
During cache read operations SR6 indicates whether the next selected page can be read from the page register (SR6 is set to ' 1 ') or not (SR6 is set to ' 0 ').

During all other operations SR6 acts as a P/E/R controller bit, which indicates whether the $P / E / R$ controller is active or inactive. When the P/E/R controller bit is set to ' 0 ', the $P / E / R$ controller is active (device is busy); when the bit is set to ' 1 ', the $P / E / R$ controller is inactive (device is ready).

### 6.7.3 P/E/R controller bit (SR5)

The program/erase/read controller bit indicates whether the P/E/R controller is active or inactive. When the P/E/R controller bit is set to ' 0 ', the $P / E / R$ controller is active (device is busy); when the bit is set to ' 1 ', the P/E/R controller is inactive (device is ready).

### 6.7.4 Error bit (SRO)

The error bit is used to identify if any errors have been detected by the P/E/R controller. The error bit is set to ' 1 ' when a program or erase operation has failed to write the correct data to the memory. If the error bit is set to ' 0 ' the operation has completed successfully.

### 6.7.5 SR4, SR3, SR2, and SR1 are reserved

Table 11. Status register bits

| Bit | Name | Logic level | Definition |
| :---: | :---: | :---: | :---: |
| SR7 | Write protection | '1' | Not protected |
|  |  | '0' | Protected |
| SR6 | Program/ erase/ read controller | '1' | P/E/R C inactive, device ready |
|  |  | '0' | P/E/R C active, device busy |
|  | Cache ready/busy | '1' | Cache register ready (cache operation only) |
|  |  | '0' | Cache register busy (cache operation only) |
| SR5 | Program/ erase/ read controller | '1' | P/E/R C inactive, device ready |
|  |  | '0' | P/E/R C active, device busy |
| SR4, SR3, SR2, SR1 | Reserved | Don't care |  |
| SR0 | Generic error | '1' | Error - operation failed |
|  |  | '0' | No error - operation successful |

### 6.8 Read electronic signature

The device contains a manufacturer code and device code. To read these codes three steps are required:

1. One bus write cycle to issue the Read Electronic Signature command (90h)
2. One bus write cycle to input the address (00h)
3. Four bus read cycles to sequentially output the data (as shown in Table 12: Electronic signature).

Table 12. Electronic signature

| Part number | byte/word 1 | byte/word 2 |  |  |
| :---: | :---: | :---: | :---: | :---: |

### 6.9 Read ONFI signature

To recognize NAND flash devices that are compatible with ONFI 1.0 command set, the Read Electronic Signature command can be issued, followed by an address of 20h. The next four-byte output is the ONFI signature, which is the ASCII encoding of the 'ONFI' word.

Reading beyond four bytes produces indeterminate values. The device remains in this state until a new command is issued.
Figure 16 describes the read ONFI signature waveforms and Table 15 defines the output bytes.

Table 15. Read ONFI signature

| Byte | Value | ASCII character |
| :---: | :---: | :---: |
| 1st byte | 4Fh | O |
| 2nd byte | 4 Eh | N |
| 3rd byte | 46 h | F |
| 4th byte | 49 h | I |
| 5th byte | Undefined | Undefined |

Figure 16. Read ONFI signature waveforms

### 6.10 Read parameter page

The Read Parameter Page command retrieves the data structure that describes the NAND flash organization, features, timings and other behavioral parameters. This data structure enables the host processor to automatically recognize the NAND flash configuration of a device. The whole data structure is repeated at least five times.

See Figure 17 for a description of the read parameter page waveforms.
The Random Data Read command can be issued during execution of the read parameter page to read specific portions of the parameter page.
The Read Status command may be used to check the status of read parameter page during execution. After completion of the Read Status command, 00h is issued by the host on the command line to continue with the data output flow for the Read Parameter Page command.

Read status enhanced is not be used during execution of the Read Parameter Page command.

Table 16 defines the parameter page data structure. For parameters that span multiple bytes, the least significant byte of the parameter corresponds to the first byte.
Values are reported in the parameter page in bytes when referring to items related to the size of data access (as in an x8 data access device). For example, the chip returns how many data bytes are in a page. For a device that supports x16 data access, the host is required to convert byte values to word values for its use. Unused fields are set to Oh.
For more detailed information about parameter page data bits, refer to ONFI Specification 1.0 section 5.4.1.

Figure 17. Read parameter page waveforms

1. $\mathrm{O}=$ optional, $\mathrm{M}=$ mandatory.

## 7 Data protection

The device has hardware features to protect against program and erase operations.
It features a Write Protect, $\overline{W P}$, pin, which can be used to protect the device against program and erase operations. It is recommended to keep $\overline{\mathrm{WP}}$ at $\mathrm{V}_{\text {IL }}$ during power-up and powerdown.

In addition, to protect the memory from any involuntary program/erase operations during power-transitions, the device has an internal voltage detector which disables all functions whenever $\mathrm{V}_{\mathrm{DD}}$ is below $\mathrm{V}_{\text {LKO }}$ (see Table 22 and Table 23).

## 8 Software algorithms

This section gives information on the software algorithms that Numonyx recommends to implement to manage the bad blocks and extend the lifetime of the NAND device.
NAND flash memories are programmed and erased by Fowler-Nordheim tunneling using a high voltage. Exposing the device to a high voltage for extended periods can cause the oxide layer to be damaged. For this reason, the number of program and erase cycles is limited (see Table 18 for value) and it is mandatory to implement error correction code algorithms to extend the number of program and erase cycles and increase data retention.
To help integrate a NAND memory into an application, Numonyx can provide a full range of software solutions: file system, sector manager, drivers and code management.

Contact the nearest Numonyx sales office or visit www.numonyx.com for more details.

### 8.1 Bad block management

Devices with bad blocks have the same quality level and the same AC and DC characteristics as devices where all the blocks are valid. A bad block does not affect the performance of valid blocks because it is isolated from the bit line and common source line by a select transistor.

The devices are supplied with all the locations inside valid blocks erased (FFh). The bad block information is written prior to shipping. Any block, where the 1st and 6th bytes (x8 device)/1st word (x16 device), in the spare area of the 1st page, does not contain FFh, is a bad block.
The bad block Information must be read before any erase is attempted as the bad block information may be erased. For the system to be able to recognize the bad blocks based on the original information it is recommended to create a bad block table following the flowchart shown in Figure 18.

### 8.2 NAND flash memory failure modes

Over the lifetime of the device additional bad blocks may develop.
To implement a highly reliable system, all the possible failure modes must be considered:

- Program/erase failure: in this case the block has to be replaced by copying the data to a valid block. These additional bad blocks can be identified as attempts to program or erase them will give errors in the status register
As the failure of a page program operation does not affect the data in other pages in the same block, the block can be replaced by re-programming the current data and copying the rest of the replaced block to an available valid block. The Copy Back Program command can be used to copy the data to a valid block. See Section 6.4: Copy back program for more details
- Read failure: in this case, ECC correction must be implemented. To efficiently use the memory space, it is recommended to recover single-bit error in read by ECC, without replacing the whole block.

Refer to Table 17 for the procedure to follow if an error occurs during an operation.

Table 17. NAND flash failure modes

| Operation | Procedure |
| :---: | :---: |
| Erase | Block replacement |
| Program | Block replacement or ECC |
| Read | ECC |

Figure 18. Bad block management flowchart

Figure 19. Garbage collection

### 8.3 Garbage collection

When a data page needs to be modified, it is faster to write to the first available page, and the previous page is marked as invalid. After several updates it is necessary to remove invalid pages to free some memory space.
To free this memory space and allow further program operations it is recommended to implement a garbage collection algorithm. In a garbage collection software the valid pages are copied into a free area and the block containing the invalid pages is erased (see Figure 19).

### 8.4 Wear-leveling algorithm

For write-intensive applications, it is recommended to implement a wear-leveling algorithm to monitor and spread the number of write cycles per block.

In memories that do not use a wear-leveling algorithm not all blocks get used at the same rate. Blocks with long-lived data do not endure as many write cycles as the blocks with frequently-changed data.

The wear-leveling algorithm ensures that equal use is made of all the available write cycles for each block. There are two wear-leveling levels:

- First level wear-leveling, new data is programmed to the free blocks that have had the fewest write cycles
- Second level wear-leveling, long-lived data is copied to another block so that the original block can be used for more frequently-changed data.

The second level wear-leveling is triggered when the difference between the maximum and the minimum number of write cycles per block reaches a specific threshold.

### 8.5 Error correction code

Users must implement an error correction code (ECC) to identify and correct errors in data stored in NAND flash memories. The ECC implemented must be able to correct 1 bit every 512 bytes. Sensible data stored in spare area must be covered by ECC as well.

### 8.6 Hardware simulation models

### 8.6.1 Behavioral simulation models

Denali Software Corporation models are platform independent functional models designed to assist customers in performing entire system simulations (typical VHDL/Verilog). These models describe the logic behavior and timings of NAND flash devices, and so allow software to be developed before hardware.

### 8.6.2 IBIS simulation models

IBIS (I/O buffer information specification) models describe the behavior of the I/O buffers and electrical characteristics of flash devices.

These models provide information such as AC characteristics, rise/fall times and package mechanical data, all of which are measured or simulated at voltage and temperature ranges wider than those allowed by target specifications.

IBIS models are used to simulate PCB connections and can be used to resolve compatibility issues when upgrading devices. They can be imported into SPICETOOLS.

## $9 \quad$ Program and erase times and endurance cycles

The program and erase times and the number of program/erase cycles per block are shown in Table 18.

Table 18. Program, erase times and program erase endurance cycles

| Parameters |  | NAND flash |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  |  |  |  |  |
|  | Min | Typ | Max |  |
| Page program time |  | 200 | 700 | $\mu \mathrm{~s}$ |
| Block erase time |  | 2 | 3 | ms |
| Program/erase cycles per block (with ECC) | 100,000 |  |  | cycles |
| Data retention | 10 |  |  | years |

## 10 Maximum ratings

Stressing the device above the ratings listed in Table 19: Absolute maximum ratings, may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the operating sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 19. Absolute maximum ratings

| Symbol | Parameter |  | Value |  | Unit |
| :---: | :--- | :---: | :---: | :---: | :---: |
|  |  |  | Min | Max |  |
|  | $\mathrm{T}_{\text {BIAS }}$ | Temperature under bias | -50 | 125 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\text {STG }}$ | Storage temperature | -65 | 150 | ${ }^{\circ} \mathrm{C}$ |  |
| $\mathrm{V}_{\text {IO }}{ }^{(1)}$ | Input or output voltage | 1.8 V devices | -0.6 | 2.7 | V |
|  |  | 3 V devices | -0.6 | 4.6 | V |
| $\mathrm{~V}_{\mathrm{DD}}$ | Supply voltage | 1.8 V devices | -0.6 | 2.7 | V |
|  |  | -0.6 | 4.6 | V |  |

1. Minimum voltage may undershoot to -2 V for less than 20 ns during transitions on input and $\mathrm{I} / \mathrm{O}$ pins. Maximum voltage may overshoot to $\mathrm{V}_{\mathrm{DD}}+2 \mathrm{~V}$ for less than 20 ns during transitions on I/O pins.

## 11 DC and AC parameters

This section summarizes the operating and measurement conditions, and the DC and AC characteristics of the device. The parameters in the DC and AC characteristics tables that follow, are derived from tests performed under the measurement conditions summarized in Table 20: Operating and AC measurement conditions. Designers should check that the operating conditions in their circuit match the measurement conditions when relying on the quoted parameters.

Table 20. Operating and AC measurement conditions

| Parameter |  | NAND flash |  | Units |
| :---: | :---: | :---: | :---: | :---: |
|  |  | Min | Max |  |
| Supply voltage ( $\mathrm{V}_{\mathrm{DD}}$ ) | 1.8 V devices | 1.7 | 1.95 | V |
|  | 3 V devices | 2.7 | 3.6 | V |

1. The time to ready depends on the value of the pull-up resistor tied to the ready/busy pin. See Figure 34, Figure 35 and Figure 36.
2. $\quad t_{W H W H}$ is the time from $\bar{W}$ rising edge during the final address cycle to $\bar{W}$ rising edge during the first data cycle.
3. During a program/erase enable operation, $t_{w w}$ is the delay from $\overline{W P}$ high to $\bar{W}$ High.

During a program/erase disable Operation, $\mathrm{t}_{\mathrm{ww}}$ is the delay from WP Low to $\overline{\mathrm{W}}$ High.
4. $t_{R L Q X}$ is valid when frequency is higher than $33 \mathrm{MHz}, \mathrm{t}_{\mathrm{RHQX}}$ is valid for frequency lower than 33 MHz .
5. $E S=$ electronic signature.

### 11.1 Ready/Busy signal electrical characteristics

Figure 35, Figure 34 and Figure 36 show the electrical characteristics for the Ready/Busy signal. The value required for the resistor $\mathrm{R}_{\mathrm{P}}$ can be calculated using the following equation:

$$
\mathrm{R}_{\mathrm{P}} \min =\frac{\left(\mathrm{V}_{\mathrm{DDmax}}-\mathrm{V}_{\mathrm{OLmax}}\right)}{\mathrm{I}_{\mathrm{OL}}{ }^{+} \mathrm{I}_{\mathrm{L}}}
$$

So,

$$
\begin{aligned}
R_{P} \min (1.8 \mathrm{~V}) & =\frac{1.85 \mathrm{~V}}{3 \mathrm{~mA}^{+} \mathrm{I}_{\mathrm{L}}} \\
\mathrm{R}_{\mathrm{P}} \min (3 \mathrm{~V}) & =\frac{3.2 \mathrm{~V}}{8 \mathrm{~mA}^{+} \mathrm{I}_{\mathrm{L}}}
\end{aligned}
$$

where $I_{L}$ is the sum of the input currents of all the devices tied to the Ready/Busy signal. $R_{P}$ max is determined by the maximum value of $t_{r}$.

### 11.2 Data protection

The Numonyx NAND device is designed to guarantee data protection during power transitions.
$A V_{D D}$ detection circuit disables all NAND operations, if $V_{D D}$ is below the $V_{L K O}$ threshold.
In the $\mathrm{V}_{\mathrm{DD}}$ range from $\mathrm{V}_{\mathrm{LKO}}$ to the lower limit of nominal range, the $\overline{\mathrm{WP}}$ pin should be kept low $\left(\mathrm{V}_{\mathrm{IL}}\right)$ to guarantee hardware protection during power transitions as shown in the below figure.

Figure 37. Data protection

## 12 Package mechanical

To meet environmental requirements, Numonyx offers these devices in RoHS compliant packages, which have a lead-free second-level interconnect. The category of second-level interconnect is marked on the package and on the inner box label, in compliance with JEDEC Standard JESD97. The maximum ratings related to soldering conditions are also marked on the inner box label.

RoHS compliant specifications are available at www.numonyx.com.

## 13 Ordering information

Table 28. Ordering information scheme

| Example: |
| :--- |
| Device type |
| NAND flash memory |
| Density |
| $01 \mathrm{G}=1$ Gbit |
| Operating voltage |

$$
\begin{aligned}
& \mathrm{R}=\mathrm{V}_{\mathrm{DD}}=1.7 \text { to } 1.95 \mathrm{~V} \\
& \mathrm{~W}=\mathrm{V}_{\mathrm{DD}}=2.7 \text { to } 3.6 \mathrm{~V}
\end{aligned}
$$

## Bus width

$3=x 8$
$4=\times 16^{(1)}$
Family identifier
B = 2112-byte/ 1056-word page

## Device options

2 = chip enable don't care enabled

## Product version

B = second version
$\mathrm{C}=$ third version

## Package

$\mathrm{N}=$ TSOP48 $12 \times 20 \mathrm{~mm}$
ZA = VFBGA63 $9 \times 11 \times 1.05 \mathrm{~mm}, 0.8 \mathrm{~mm}$ pitch
$Z F=V F B G A 1538 \times 9 \times 0.9 \mathrm{~mm} .0 .5 \mathrm{~mm}$ pitch
Temperature range
$5=-25$ to $85^{\circ} \mathrm{C}$
$6=-40$ to $85^{\circ} \mathrm{C}$
Option
E = RoHS compliant package, standard packing
F = RoHS compliant package, tape \& reel packing

1. x16 organization only available for MCP products.

Note: $\quad$ Not all combinations are necessarily available. For a list of available devices or for further information on any aspect of these products, please contact your nearest Numonyx sales office.

## 14 Revision history

Table 29. Document revision history

| Date | Version | Changes |
| :---: | :---: | :--- |
| 24-Jun-2008 | 1 | Initial release. |
| 16-Jan-2009 | 2 | Modified Section 8.5: Error correction code, Figure 34: Ready/Busy AC <br> waveform, and Figure 36: Resistor value versus waveform timings for <br> Ready/Busy signal. Removed Figure 19: Error detection. |
| 23-Feb-2009 | 3 | Modified Figure 7: Read operations, Table 12: Electronic signature and <br> Table 16: Parameter page data structure. Added security features on <br> the cover page and in Section 1: Description. <br> Removed references to ECOPACK packages throughout the document. |
| 08-Jun-2009 | 4 | Document status promoted from preliminary data to full datasheet. <br> Modified dimension A2 of the VFBGA63 package in Table 27: <br> VFBGA63 9 $11 \times 1.05$ mm $-6 \times 8+15,0.80$ mm pitch, package <br> mechanical data. |
| 29-Jan-2010 | 5 | Added references to the VFBGA153 8 $\times 9 \times 0.9$ mm package <br> throughout the document. Removed temperature range 1 and added <br> temperature range 5 in Table 28: Ordering information scheme. |
