KAE-08151

2856 (H) x 2856 (V) Interline Transfer EMCCD Image Sensor

The KAE−08151 Image Sensor is a 8.1 Mp, 4/3″ format, Interline Transfer EMCCD image sensor that provides exceptional imaging performance in extreme low light applications. Each of the sensor's four outputs incorporates both a conventional horizontal CCD register and a high gain EMCCD register.

An intra-scene switchable gain feature samples each charge packet on a pixel-by-pixel basis. This enables the camera system to determine whether the charge will be routed through the normal gain output or the EMCCD output based on a user selectable threshold. This feature enables imaging in extreme low light, even when bright objects are within a dark scene, allowing a single camera to capture quality images from sunlight to starlight.

This image sensor is based on an advanced 5.5-micron Interline Transfer CCD Platform, and features extended dynamic range, excellent imaging performance, and a flexible readout architecture that enables use of 1, 2, or 4 outputs. A vertical overflow drain structure suppresses image blooming, provides excellent MTF, and enables electronic shuttering for precise exposure.

Figure 1. KAE−08151 Interline Transfer EMCCD Image Sensor

Features

- Intra-Scene Switchable Gain
- Wide Dynamic Range
- Low Noise Architecture
- Exceptional Low Light Imaging
- Global Shutter
- Excellent Image Uniformity and MTF
- Bayer Color Pattern and Monochrome

Applications

- Surveillance
- Scientific Imaging
- Medical Imaging
- Intelligent Transportation

ORDERING INFORMATION

See detailed ordering and shipping information on page 2 of this data sheet.

Table 1. GENERAL SPECIFICATIONS

Parameter	Typical Value
Architecture	Interline CDD; with EMCCD
Total Number of Pixels	2928 (H) $\times$ 2904 (V)
Number of Effective Pixels	2880 (H) $\times$ 2880 (V)
Number of Active Pixels	2856 (H) $\times$ 2856 (V)
Pixel Size	5.5 μm (H) $\times$ 5.5 μm (V)
Active Image Size	15.71 mm (H) $\times$ 15.71 mm (V) 22.22 mm (Diagonal) 4/3″ Optical Format
Aspect Ratio	1:1
Number of Outputs	1, 2, or 4
Charge Capacity	20,000 e$^-$
Output Sensitivity	44 μV/e$^-$
Quantum Sensitivity Mono/Color (RGB)	50% / 33%, 41%, 43%
Readout Noise (20 MHz) Normal Mode (1$\times$ Gain) Intra-Scene Mode (20$\times$ Gain)	9 e$^-$ rms < 1 e$^-$ rms
Dark Current (0°C) Photodiode, VCCD	< 0.1, 6 e$^-$/s
Dynamic Range Normal Mode (1$\times$ Gain) Intra-Scene Mode (20$\times$ Gain)	66 dB 86 dB
Charge Transfer Efficiency	0.999999
Blooming Suppression	> 1000 X
Smear	−100 dB
Image Lag	< 1 e$^-$
Maximum Pixel Clock Speed	40 MHz for horiz. binning
Maximum Frame Rate Normal Gain Mode, Intra-Scene Mode	14 fps (40 MHz), 8 fps (20 MHz)
Package Type	155 Pin PGA
Cover Glass	Clear Glass, Taped MAR Glass, Sealed

NOTE: All Parameters are specified at T = −10°C unless otherwise noted.

ORDERING INFORMATION
US export controls apply to all shipments of this product designated for destinations outside of the US and Canada, requiring ON Semiconductor to obtain an export license from the US Department of Commerce before image sensors or evaluation kits can be exported.

Table 2. ORDERING INFORMATION − KAE−08151 IMAGE SENSOR

Part Number	Description	Marking Code
KAE−08151−ABA−JP−FA	Monochrome, Microlens, PGA Package, Taped Clear Cover Glass (No Coatings), Standard Grade	KAE−08151−ABA Serial Number
KAE−08151−ABA−JP−EE	Monochrome, Microlens, PGA Package, Taped Clear Cover Glass (No Coatings), Engineering Grade	
KAE−08151−FBA−JP−FA	Color (Bayer RGB), Microlens, PGA Package, Taped Clear Cover Glass (No Coatings), Standard Grade	KAE−08151−FBA Serial Number
KAE−08151−FBA−JP−EE	Color (Bayer RGB), Microlens, PGA Package, Taped Clear Cover Glass (No Coatings), Engineering Grade	
KAE−08151−ABA−SP−FA	Monochrome, Microlens, PGA Package with Integrated TEC, Taped Clear Cover Glass (No Coatings), Standard Grade	KAE−08151−ABA Serial Number
KAE−08151−ABA−SP−EE	Monochrome, Microlens, PGA Package with Integrated TEC, Taped Clear Cover Glass (No Coatings), Engineering Grade	
KAE−08151−FBA−SP−FA	Color (Bayer RGB), Microlens, PGA Package with Integrated TEC, Taped Clear Cover Glass (No Coatings), Standard Grade	KAE−08151−FBA Serial Number
KAE−08151−FBA−SP−EE	Color (Bayer RGB), Microlens, PGA Package with Integrated TEC, Taped Clear Cover Glass (No Coatings), Engineering Grade	
KAE−08151−ABA−SD−FA	Monochrome, Microlens, PGA Package with Integrated TEC, Sealed MAR Cover Glass, Standard Grade	KAE−08151−ABA Serial Number
KAE−08151−ABA−SD−EE	Monochrome, Microlens, PGA Package with Integrated TEC, Sealed MAR Cover Glass, Engineering Grade	
KAE−08151−FBA−SD−FA	Color (Bayer RGB), Microlens, PGA Package with Integrated TEC, Sealed MAR Cover Glass, Standard Grade	KAE−08151−FBA Serial Number
KAE−08151−FBA−SD−EE	Color (Bayer RGB), Microlens, PGA Package with Integrated TEC, Sealed MAR Cover Glass, Engineering Grade	

See the ON Semiconductor *Device Nomenclature* document (TND310/D) for a full description of the naming convention used for image sensors. For reference documentation, including information on evaluation kits, please visit our web site at www.onsemi.com.

Warning

The KAE−08151−ABA−SD and KAE−08151−FBA−SD packages have an integrated thermoelectric cooler (TEC) and have epoxy−sealed cover glass. The seal formed is non−hermetic, and may allow moisture ingress over time, depending on the storage environment.

As a result, care must be taken to avoid cooling the device below the dew point inside the package cavity, since this may result in moisture condensation.

For all KAE−08151 configurations, no warranty, expressed or implied, covers condensation.

DEVICE DESCRIPTION

Architecture
Figure 2. Block Diagram

Dark Reference Pixels

There are 12 dark reference rows at the top and bottom of the image sensor, as well as 24 dark reference columns on the left and right sides. However, the rows and columns at the perimeter edges should not be included in acquiring a dark reference signal, since they may be subject to some light leakage.

Active Buffer Pixels

12 unshielded pixels adjacent to any leading or trailing dark reference regions are classified as active buffer pixels. These pixels are light sensitive but are not tested for defects and non-uniformities.

Image Acquisition

An electronic representation of an image is formed when incident photons falling on the sensor plane create electron-hole pairs within the individual silicon photodiodes. These photoelectrons are collected locally by the formation of potential wells at each photo-site. Below photodiode saturation, the number of photoelectrons collected at each pixel is linearly dependent upon light level and exposure time and non-linearly dependent on wavelength. When the photodiodes charge capacity is reached, excess electrons are discharged into the substrate to prevent blooming.

2. Per color
3. Value is over the range of 10% to 90% of photodiode saturation.
4. The operating value of the substrate reference voltage, V_{AB}, can be read from VSUBREF.
5. At 20 MHz.
6. Uses 20 LOG (P_{Ne} / n_{e-T}).
7. Calculated from $f_{-3dB} = 1 / 2n \cdot R_{OUT} \cdot C_{LOAD}$ where C_{LOAD} = 5 pF.
8. The output-to-output gain differences may be adjusted by independently adjusting the EMCCD amplitude for each output.

DEFECT DEFINITIONS

Table 7. DEFECT DEFINITIONS

Description	Definition	Maximum Number Allowed
Major Dark Field Defective Bright Pixel	Defect ≥ 30 mV deviation from the mean, for all pixels in the active image area.	80
Major Bright Field Defective Dark Pixel	≥ 12%	
Minor Dark Field Defective Bright Pixel	Defect ≥ 15 mV deviation from the mean, for all pixels in the active image area.	800
Cluster Defect	A group of 2 to 10 contiguous major defective pixels, with no more than 3 adjacent defects horizontally.	15
Column Defect	A group of more than 10 contiguous major dark defective pixels along a single column or 10 contiguous bright defective pixels along a single column.	0

9. Low exposure dark column defects are not counted at temperatures above −10°C
10. For the color device, a bright field defective pixel deviates by 12% with respect to pixels of the same color.
11. Column and cluster defects are separated by no less than 2 good pixels in any direction (excluding single pixel defects).

OPERATION

Absolute Maximum Ratings

Absolute maximum rating is defined as a level or condition that should not be exceeded at any time per the description. If the level or the condition is exceeded, the device will be degraded and may be damaged. Operation at these values will reduce MTTF.

Table 8. ABSOLUTE MAXIMUM RATINGS

Description	Symbol	Minimum	Max.	Unit
Operating Temperature (Note 12)	T_{OP}	−40	+40	°C
Humidity (Note 13)	RH	+5	+90	%
Output Bias Current (Note 14)	I_{OUT}	–	5	mA
Off-chip Load	CL	–	10	pF

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.
12. Noise performance will degrade at higher temperatures.
13. T = 25°C. Excessive humidity will degrade MTTF.
14. Total for all outputs. Maximum current is −15 mA for each output. Avoid shorting output pins to ground or any low impedance source during operation. Amplifier bandwidth increases at higher current and lower load capacitance at the expense of reduced gain (sensitivity).

Table 9. ABSOLUTE MAXIMUM VOLTAGE RATINGS BETWEEN PINS AND GROUND

Description	Minimum	Max.	Unit

15. Refer to Application Note *Using Interline CCD Image Sensors in High Intensity Visible Lighting Conditions.*
16. The measured value for VSUBREF is a diode drop higher than the recommended minimum VSUB bias.

Power Up and Power Down Sequence

SUB and ESD power up first, then power up all other biases in any order. No pin may have a voltage less than ESD at any time. All HCCD pins must be greater than or equal to GND at all times. The SUBREF pin will not become valid until VDD15ac and VDD15bd have been powered. Therefore the SUB voltage cannot be directly derived from the SUBREF pin. The SUB pin should be at least 4 V before powering up VDD2(a,b,c,d) and VDD3(a,b,c,d).

The sequence for power down should be the reverse of that for power up, so that the SUB and ESD biases are shut off last.
Figure 8. Power Up Timing Diagram

Table 10. DC BIAS OPERATING CONDITIONS

Description	Pins	Symbol	Min.	Nom.	Max.	Unit	Maximum DC Current
Output Amplifier Return	VSS1(a,b,c,d)	VSS1	−8.3	−8.0	−7.7	V	4 mA
Output Amplifier Supply	VDD1(a,b,c,d)	VDD1	4.5	5.0	6.0	V	15 mA
Output Amplifier Supply	VDD2(a,b,c,d), VDD3(a,b,c,d)	VDD	+14.7	+15.0	+15.3	V	37.0 mA

Ground	GND	GND	0.0	0.0	0.0	V	17.0 mA
Substrate (Notes 18 and 19)	SUB	VSUB	6.0	VSUBREF − 0.5	VSUBREF + 28	V	Up to 1 mA (Determined by Photocurrent)
ESD Protection Disable	ESD	ESD	−8.3	−8.0	−7.7	V	2 mA
Output Bias Current	VOUT1(a,b,c,d), VOUT2(a,b,c,d), VOUT3(a,b,c,d)	I$_{OUT}$	2.0	2.5	5.0	mA	

17. VDD15ac and VDDD15bd bias pins must be maintained at 15 V during operation.
18. For each image sensor, the voltage output on the VSUBREF pin is programmed to be one diode drop, 0.5 V, above the nominal VSUB voltage. So, the applied VSUB should be one diode drop (0.5 V) lower than the VSUBREF value measured on the device, when VDD2(a,b,c,d) and VDD3(a,b,c,d) are at the specified voltage. This value corresponds to the VAB printed on the label for each sensor and applies to operation at 0°C. (For other temperatures, there is a temperature dependence of approximately 0.01 V/degree.) It is noted that VSUBREF is unique to each image sensor and may vary from 6.5 to 10.0 V. In addition, the output impedance of VSUBREF is approximately 100 k.
19. Caution: The EMCCD register must NOT be clocked while the electronic shutter pulse is high.

Figure 10. EMCCD Clock Adjustable Levels

For the EMCCD clocks, each quadrant must have independently adjustable high levels. All quadrants have a common low level of GND. The high level adjustments must be software controlled to balance the gain of the four outputs.
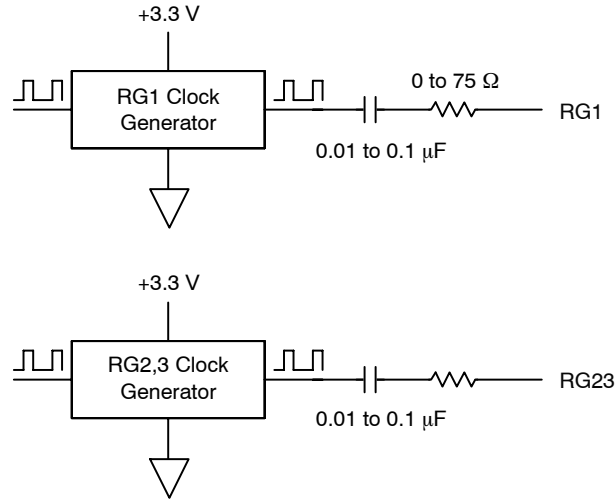

Figure 11. Reset Clock Drivers

The reset clock drivers must be coupled by capacitors to the image sensor. The capacitors can be anywhere in the range 0.01 to 0.1 μF. The damping resistor values would vary between 0 and 75 Ohms depending on the layout of the circuit board.

Table 12. VCCD

Pin	Function	Low	Nominal	High
V1T, V1B, V2T, V2B, V3T, V3B, V4T, V4B	Vertical CCD Clock, Low Level	−8.0	−8.0	−6.0

Device Identification

The device identification pin (DevID) may be used to determine which ON Semiconductor 5.5 micron pixel interline CCD sensor is being used.

Table 14. DEVICE IDENTIFICATION VALUES

Description	Pins	Symbol	Min.	Nom.	Max.	Unit	Maximum DC Current
Device Identification (Notes 23, 24 and 25)	ID	ID	8,000	10,000	12,000	Ω	0.3 mA

23. Nominal value subject to verification and/or change during release of preliminary specifications.
24. If the Device Identification is not used, it may be left disconnected.
25. After Device Identification resistance has been read during camera initialization, it is recommended that the circuit be disabled to prevent localized heating of the sensor due to current flow through the R_DeviceID resistor.

Recommended Circuit
Figure 12. Device Identification Recommended Circuit

THEORY OF OPERATION

Image Acquisition
Figure 13. Illustration of Two Columns and Three Rows of Pixels

This image sensor is capable of detecting up to 20,000 electrons with a small signal noise floor of 1 electron all within one image. Each 5.5 μm square pixel, as shown in Figure 13 above, consists of a light sensitive photodiode and a portion of the vertical CCD (VCCD). Not shown is a microlens positioned above each photodiode to focus light away from the VCCD and into the photodiode. Each photon incident upon a pixel will generate an electron in the photodiode with a probability equal to the quantum efficiency.

The photodiode may be cleared of electrons (electronic shutter) by pulsing the SUB pin of the image sensor up to a voltage of 30 V to 40 V (VSUBREF + 22 to VSUBREF +28 V) for a time of at least 1 μs. When the SUB pin is above 30 V, the photodiode can hold no electrons, and the electrons flow downward into the substrate. When the voltage on SUB drops below 30 V, the integration of electrons in the photodiode begins. The HCCD clocks should be stopped when the electronic shutter is pulsed, to avoid having the large voltage pulse on SUB coupling into the video outputs and altering the EMCCD gain.

It should be noted that there are certain conditions under which the device will have no anti-blooming protection: when the V1T and V1B pins are high, very intense illumination generating electrons in the photodiode will flood directly into the VCCD. When the electronic shutter pulse overlaps the V1T and V1B high-level pulse that transfers electrons from the photodiode to the VCCD, then photo-electrons will flow to the substrate and not the VCCD. This condition may be desirable as a means to obtain very short integration times.

The VCCD is shielded from light by metal to prevent detection of more photons. For very bright spots of light, some photons may leak through or around the metal light shield and result in electrons being transferred into the VCCD. This is called image smear.

Image Readout

At the start of image readout, the voltage on the V1T and V1B pins is pulsed from 0 V up to the high level for at least 1 μs and back to 0 V, which transfers the electrons from the photodiodes into the VCCD. If the VCCD is not empty, then the electrons will be added to what is already in the VCCD. The VCCD is read out one row at a time. During a VCCD row transfer, the HCCD clocks are stopped. All gates of type H1 stop at the high level and all gates of type H2 stop at the low level. After a VCCD row transfer, charge packets of electrons are advanced one pixel at a time towards the output amplifiers by each complimentary clock cycle of the H1 and H2 gates.

The charge multiplier has a maximum charge handling capacity (after gain) of 20,000 electrons. This is not the average signal level. It is the maximum signal level. Therefore, it is advisable to keep the average signal level at 15,000 electrons or less to accommodate a normal distribution of signal levels. For a charge multiplier gain of 20x, no more than 15,000/20 = 750 electrons should be allowed to enter the charge multiplier. Overfilling the charge multiplier beyond 20,000 electrons will shorten its useful operating lifetime.

To prevent overfilling the charge multiplier, a non-destructive floating gate output amplifier (VOUT1) is

provided on each quadrant of the image sensor as shown in Figure 14 below.
Figure 14. The Charge Transfer Path of One Quadrant

The non-destructive floating gate output amplifier is able to sense how much charge is present in a charge packet without altering the number of electrons in that charge packet. This type of amplifier has a low charge-to-voltage conversion gain (about 6.2 µV/e) and high noise (about 50 electrons), but it is being used only as a threshold detector, and not an imaging detector. Even with 50 electrons of noise, it is adequate to determine whether a charge packet is greater than or less than the recommended threshold of 150 electrons.

After one row has been transferred from the VCCD into the HCCD, the HCCD clock cycles should begin. After 12 clock cycles, the first dark VCCD column pixel will arrive at VOUT1. After another 24 (34 total) clock cycles, the first photo-active charge packet will arrive at VOUT1.

The transfer sequence of a charge packet through the floating gate amplifier is shown in Figure 15 below. The time steps of this sequence are labeled A through D, and are indicated in the timing diagram shown as Figure 16. The RG1 gate is pulsed high during the time that the H2X gate is pulsed high. This holds the floating gate at a constant voltage so the H2X gate can pull the charge packet out of the floating gate. The RG1 pulse should be at least as wide as the H2X pulse, and the H2X pulse width should be at least 12 ns. The rising edge of H2X relative to the falling edge of H1S is critical, specifically, the H2X pulse cannot begin its rising edge transition until the H1S edge is less than 0.4 V. If the H2X rising edge comes too soon then there may be some backward flow of charge for signals above 10,000 electrons.
NOTE: The differently shaded rectangles represent two separate charge packets. The direction of charge transfer is from right to left. Gates after H2X are connected to H1 or H2. Gates before H2X are connected to H1S or H2S.

Figure 15. Charge Package Transfer Sequence through the Floating Gate Amplifier
Figure 16. Timing Signals that Control the Transfer of Charge through the Floating Gate Amplifier

The charge packet is transferred under the floating gate on the falling edge of H2L. When this transfer takes place the floating gate is not connected to any voltage source. The presence of charge under the gate causes a change in voltage on the floating gate according to $V = Q/C$, where Q is the size of the charge packet and C is the capacitance of the floating gate. With an output sensitivity of 6.2 µV/e-, each electron on the floating gate would give a 6.2 µV change in VOUT1 voltage. Therefore if the decision threshold is to only allow charge packets of 150 electrons or less into the charge multiplier, this would correspond to $150 \times 6.2 = 930$ µV. If the video output is less than 930 µV, then the camera must set the timing of the H2SW2 and H2SW3 pins to route the charge packet to the charge multiplier. This action must take place 28 clock cycles after the charge packet was under the floating gate amplifier. The 28 clock cycle delay is to allow for pipeline delays of the A/D converter inside the analog front end. The timing generator must examine the output of the analog front end and dynamically alter the timing on H2SW2 and H2SW3. To route a charge packet to the charge multiplier (VOUT3), H2SW2 is held at GND and H2SW3 is clocked with the same timing as H2 for that one clock cycle. To route a charge packet to the low gain output amplifier (VOUT2), H2SW3 is held at GND and H2SW2 is clocked with the same timing as H2S for that one clock cycle.

EMCCD OPERATION

NOTE: Charge flows from right to left.
Figure 17. The Charge Multiplication Process

The charge multiplication process, shown in Figure 17 above, begins at time step A, when an electron is held under the H1SEM gate. The H2BEM and H1BEM gates block the electron from transferring to the next phase until the H2SEM has reached its maximum voltage. When the H2BEM is clocked from 0 to +5 V, the channel potential under H2BEM increases until the electron can transfer from H1SEM to H2SEM. When the H2SEM gate is above 10 V, the electric field between the H2BEM and H2SEM gates gives the electron enough energy to free a second electron which is collected under H2SEM. Then the voltages on H2BEM and H2SEM are both returned to 0 V at the same time that H1SEM is ramped up to its maximum voltage. Now the process can repeat again with charge transferring into the H1SEM gate.

The alignment of clock edges is shown in Figure 18. The rising edge of the H1BEM and H2BEM gates must be delayed until the H1SEM or H2SEM gates have reached their maximum voltage. The falling edge of H1BEM and H2BEM must reach 0 V before the H1SEM or H2SEM reach 0 V. There are a total of 1,800 charge multiplying transfers through the EMCCD on each quadrant.
Figure 18. The Timing Diagram for Charge Multiplication

The amount of gain through the EMCCD will depend on temperature and H1SEM and H2SEM voltage as shown in Figure 19. Gain also depends on substrate voltage, as shown in Figure 20, and on the input signal, as shown in Figure 21.
NOTE: This figure represents data from only one example image sensor, other image sensors will vary.

Figure 19. The Variation of Gain vs. EMCCD High Voltage and Temperature
NOTE: EMCCD gain is not constant with substrate voltage.

Figure 20. The Required EMCCD Voltage for Gain of 20x vs. Substrate Voltage
NOTE: The EMCCD voltage was set to provide 20x gain with an input of 180 electrons.

Figure 21. EMCCD Gain vs. Input Signal

If more than one output is used, then the EMCCD high level voltage must be independently adjusted for each quadrant. This is because each quadrant will require a slightly different voltage to obtain the same gain. In addition, the voltage required for a given gain differs unpredictably from one image sensor to the next, as in Figure 22. Because of this, the gain vs. voltage relationship must be calibrated for each image sensor, although within each quadrant, the H1SEM and H2SEM high level voltage should be equal.
Figure 22. An Example Showing How Two Image Sensors Can Have Different Gain vs. Voltage Curves

The effective output noise of the image sensor is defined as the noise of the output signal divided by the gain. This is measured with zero input signal to the EMCCD. Figure 23 shows the EMCCD by itself has a very low noise that goes as the noise at gain = 1 divided by the gain. The EMCCD has very little clock-induced charge and does not require elaborate sinusoidal waveform clock drivers. Simple square wave clock drivers with a resistor between the driver and sensor for a small RC time constant are all that is needed. However, the pixel array may acquire spurious charge as a function of VCCD clock driver characteristics.
NOTE: The data represented by this chart includes noise from dark current and spurious charge generation.

Figure 23. EMCCD Output Noise vs. EMCCD Gain in Single Output Mode from −30°C to +10°C

Because of these pixel array noise sources, it is recommended that the maximum gain used be 100x, which typically gives a noise floor between 0.2 e$^-$ and 0.4 e$^-$ at −10°C. Using higher gains will provide limited benefit and will degrade the signal to noise ratio due to the EMCCD excess noise factor. Furthermore, the image sensor is not limited by dark current noise sources when the temperature is below −30°C. Therefore, cooling below −30°C will not provide a significant improvement to the noise floor, with the negative consequence that lower temperatures increase the probability of poor charge transfer.

CAUTION: The EMCCD should not be operated near saturation for an extended period, as this may result in gain aging and permanently reduce the gain. It should be noted that device degradation associated with gain aging is not covered under the device warranty.

Operating Temperature

The reasons for lowering the operating temperature are to reduce dark current noise and to reduce image defects. The average dark signal from the VCCD and photodiodes must be less than 1 e$^-$ in order to have a total system noise less than 1 e$^-$ when using the EMCCD. The recommended operating temperature is −10°C. This represents the best compromise of low noise performance vs. complexity of cooling the image sensor. Operation below −30°C is not recommended, and temperatures below −30°C may result in poor charge transfer in the HCCD. Operation above 0°C may result in excessive dark current noise.

Charge Switch Threshold

The floating gate output amplifier (VOUT1) is used to select the routing of a pixel charge packet at the charge switch. Pixels with large signals should be routed to the normal floating diffusion amplifier at VOUT2. Pixels with small signals should be routed to the EMCCD and VOUT3. The routing of pixels is controlled by the timing on H2SW2 and H2SW3. The optimum signal threshold for that transition between VOUT2 and VOUT3 is approximately 3 times the floating gate amplifier noise, or 150 e$^-$. Sending signals larger than 150 e$^-$ into the EMCCD will produce images with lower signal to noise ratio than if they were read out of the normal floating diffusion output of VOUT2.

TIMING DIAGRAMS

Pixel Timing
NOTE: The minimum time for one pixel is 50 ns.

Figure 24. Pixel Timing Pattern P1

Black, Clamp, VOUT1, VOUT2, and VOUT3
Alignment at Line Start

The black level clamping operation of the analog front end (AFE) should take place within the first 28 clock cycles of every row. This applies to all modes of operation.

No Horizontal Charge Binning
**Figure 25. The Alignment of Pixels within the HCCD and EMCCD when Transferring an Entire Line to the Left Side Outputs**

KAE−08151

In Figure 25, it is shown that the first photo-active pixel arrives at VOUT1 after 36 (12 + 24) H2L clock cycles. The first photo-active pixel arrives at VOUT2 after 68 (4 + 28 + 12 + 24) H2L clock cycles. The first photo-active pixel arrives at VOUT3 after 64 (28 + 12 + 24) H2L clock cycles.

The pixels at VOUT3 are delayed by one line relative to when pixels arrive at VOUT2. Every line must have exactly 3084 clock cycles to preserve the alignment of pixels within the EMCCD register.
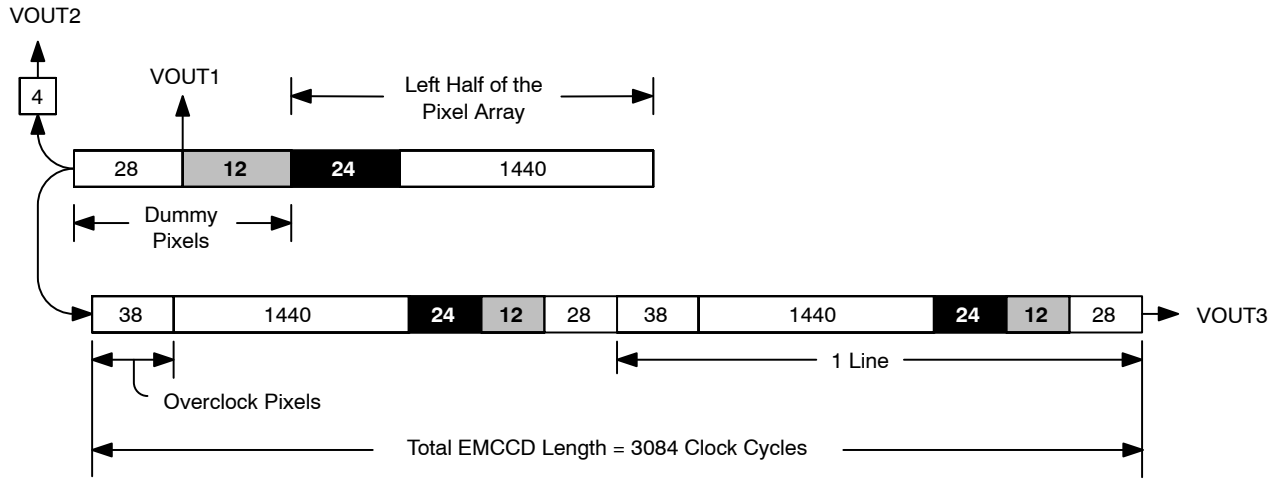

Figure 26. The Alignment of Pixels within the HCCD and EMCCD when Transferring the Left Half of the Line to the A and C Outputs and the Right Half of the Line to the B and D Outputs

In Figure 26, it is shown that the pixels at VOUT3 are delayed by two lines relative to when pixels arrive at VOUT2. Every line must have exactly 1542 clock cycles to preserve the alignment of pixels within the EMCCD register.
Figure 27. The Video Output Waveforms a the Start of Each Line with No Horizontal Charge Binning, for 1, 2, or 4-Output Mode

2x Horizontal Charge Binning

In 2x horizontal binning mode, the H1S, H2S, H1B, and H2B clocks are all run at 40 MHz. The timing of all other HCCD clocks is not changed.

Figure 28. The Alignment of Pixels within the HCCD and EMCCD for 2x Horizontal Charge Binning when Transferring an Entire Line to the Left Side Outputs

In Figure 28, the first photo-active pixel is shown arriving at VOUT1 after 18 (6 + 12) H2L clock cycles and 36 H2S clock cycles. The 28 dummy pixels after VOUT1 are not binned, only pixels before VOUT1. The first photo-active pixel arrives at VOUT2 after 50 (4 + 28 + 6 + 12) H2L clock cycles and 68 H2S clock cycles. The first photo-active pixel

arrives at VOUT3 after 46 (28 + 6 + 12) H2L clock cycles and 64 H2S clock cycles. The pixels at VOUT3 are delayed by two lines relative to when pixels arrive at VOUT2. Every line must have exactly 1542 H2L clock cycles to preserve the alignment of pixels within the EMCCD register.

Figure 29. The Alignment of Pixels within the HCCD and EMCCD for 2x Horizontal Charge Binning when Transferring the Left Half of a Line to the A and C Outputs and the Right Half of the Line to the B and D Outputs

In Figure 29, it is shown that the pixels at VOUT3 are delayed by 4 lines relative to when pixels arrive at VOUT2.

Every line must have exactly 771 H2L clock cycles to preserve the alignment of pixels within the EMCCD register.
Figure 30. The Video Output Waveforms at the Start of Each Line with 2x Horizontal Charge Binning, for 1, 2, or 4-Output Mode

3x Horizontal Charge Binning

In 3x horizontal binning mode, the H1S, H2S, H1B, and H2B clocks are all run at 60 MHz. The timing of all other HCCD clocks is not changed. In this mode the HCCD cannot be operated split left/right. 6 half lines of charge cannot fit within the EMCCD register. Only 1 output mode or 2 output mode (split top/bottom) is possible.

Figure 31. The Alignment of Pixels within the HCCD and EMCCD for 3x Horizontal Charge Binning when Transferring an Entire Line to the Left Side Outputs

The first photo-active pixel arrives at VOUT1 after 12 (4 + 8) H2L clock cycles and 36 H2S clock cycles. The 28 dummy pixels after VOUT1 are not binned, only pixels before VOUT1. The first photo−active pixel arrives at VOUT2 after 44 (4 + 28 + 4 + 8) H2L clock cycles and 68 H2S clock cycles. The first photo-active pixel arrives at VOUT3 after 40 (28 + 4 + 8) H2L clock cycles and 64 H2S clock cycles. The pixels at VOUT3 are delayed by 3 lines relative to when pixels arrive at VOUT2. Every line must have exactly 1028 clock cycles to preserve the alignment of pixels within the EMCCD register.
Figure 32. The Video Output Waveforms at the Start of Each Line with 3x Horizontal Charge Binning. This is for 1 or 2-Output Mode

4x Horizontal Charge Binning

In 4x horizontal binning mode, the H1S, H2S, H1B, and H2B clocks are all run at 80 MHz. The timing of all other HCCD clocks is not changed. In this mode the HCCD cannot be operated split left/right. 8 half lines of charge cannot fit within the EMCCD register. Only 1 output mode or 2 output mode (split top/bottom) is possible.

Figure 33. The Alignment of Pixels within the HCCD and EMCCD for 4x Horizontal Charge Binning when Transferring an Entire Line to the Left Side Outputs

In Figure 33, it is shown that the first photo-active pixel arrives at VOUT1 after 9 (3 + 6) H2L clock cycles and 36 H2S clock cycles. The 28 dummy pixels after VOUT1 are not binned, only pixels before VOUT1. The first photo-active pixel arrives at VOUT2 after 41 (4 + 28 + 3 + 6) H2L clock cycles and 68 H2S clock cycles. The first photo-active pixel arrives at VOUT3 after 37 (28 + 3 + 6) H2L clock cycles and 64 H2S clock cycles. The pixels at VOUT3 are delayed by 3 lines relative to when pixels arrive at VOUT2. Every line must have exactly 771 clock cycles to preserve the alignment of pixels within the EMCCD register.

Electronic Shutter
Figure 39. Electronic Shutter Timing Pattern S1

WARNING: The EMCCD register must not be clocked while the electronic shutter pulse is high.

HCCD and EMCCD Clocks for Electronics Shutter

   The HCCD and EMCCD clocks must be static during the frame, line, and electronic shutter timing sequences.

Table 16. HCCD AND EMCCD CLOCKS FOR ELECTRONICS SHUTTER

Clocks	State
H1S, H1, H1SEM, H1BEM	High
H2S, H2, H2SW, H2L, H2X, H2SEM, H2BEM	Low

HCCD Timing

To reverse the direction of charge transfer in a Horizontal CCD, the timing patterns of the H1B and H2B inputs of that HCCD are exchanged. If a HCCD is not used, all of its gates are to be held at the high level.

Table 17. HCCD TIMING

Mode	HCCD a, b Timing	HCCD c, d Timing
Single	H1Ba = H2Bb = H1Sa = H1Sb H2Ba = H1Bb = H2Sa = H2Sb	3.3 V
Dual	H1Ba = H1Bb = H1Sa = H1Sb H2Ba = H2Bb = H2Sa = H2Sb	3.3 V
Quad	H1Ba = H1Bb = H1Sa = H1Sb H2Ba = H2Bb = H2Sa = H2Sb	H1Bc = H1Bd = H1Sc = H1Sd H2Bc = H2Bd = H2Sc = H2Sd
Figure 40. The HCCD Timing for the Four Charge Binning Modes

Binning Mode	Frequency (MHz)	All Out Left Side	Left Right Split
All Modes	20	3084	1542
1x	20	3084	1542
2x	40	1542	771
3x	60	1028	N/A
4x	80	771	N/A

Table 18. FRAME RATES

Binning Mode	Single	Dual (Left/Right)	Dual (Top/Bottom)	Quad	Unit
1×1	2.1	4.0	4.2	7.9	fps
2×2	7.2	11.9	14.3	23.8	fps
3×3	12.9	N/A	25.8	N/A	fps
4×4	17.9	N/A	35.8	N/A	fps

Image Exposure and Readout

The flowchart for image exposure and readout is shown in the figure below. The electronic shutter timing may be omitted to obtain an exposure time equal to the image read out time. NH is the number of horizontal clocks, NEXP is the number of lines exposure time and NV is the number of VCCD clock cycles (row transfers).

Table 19. IMAGE READOUT TIMING

Mode	NH	NV	Line Timing	Frame Timing
Single	3084	2904	L1	F1
Dual (Left/Right)	1542	2904	L1	F1
Dual (Top/Bottom)	3084	1452	L2	F2
Quad	1542	1452	L2	F2
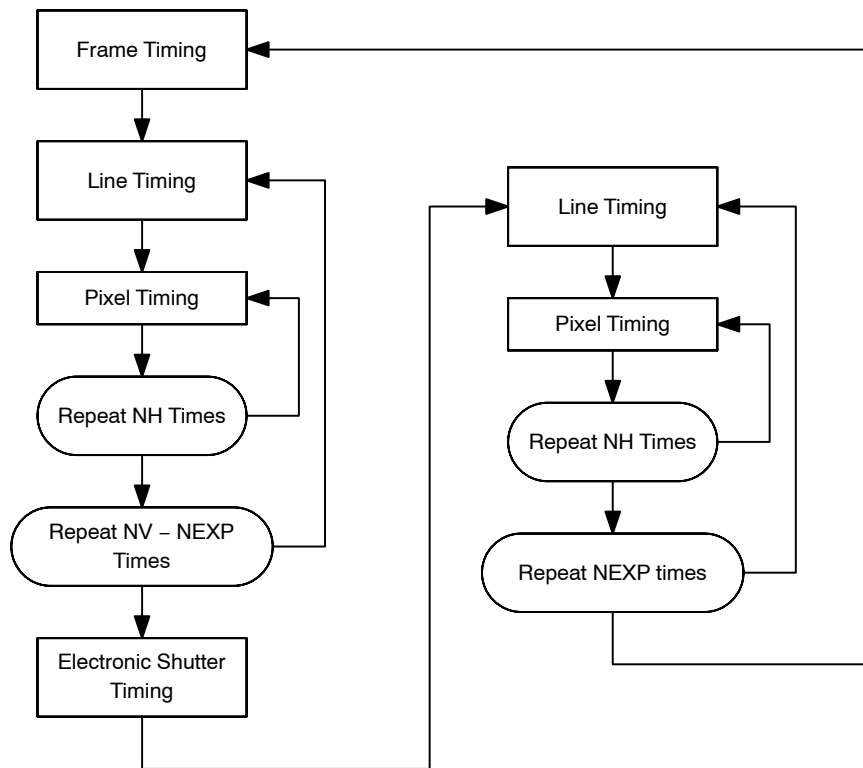

Figure 41. The Image Readout Timing Flow Chart

KAE−08151

Long Integrations and Readout

For extended integrations the output amplifiers need to be powered down. When powered up, the output amplifiers emit near infrared light that is sensed by the photodiodes. It will begin to be visible in images of 30 second integrations or longer.

Figure 42. Timing Flow Chart for Long Integration Time

To power down the output amplifiers set VDD1 and VSS1 to 0 V, and VDD2(a,b,c,d) and VDD3(a,b,c,d) to +5 V VDD2 or VDD3 must not be set to 0 V during the integration of an image. During the time the VDD2 and VDD3 supplies are reduced to +5 V the VDD15 pin is to be kept at +15 V. The substrate voltage reference output SUBV will be valid as long as VDD15 is powered. The HCCD and EMCCD may be continue to clock during integration. If they are stopped during integration then the EMCCD should be re-started at +7 V amplitude to flush out any undesired signal before increasing the voltage to charge multiplying levels.

THERMOELECTRIC COOLER

Representative performance plots for the TEC are shown below:

Performance Plots of Integrated TECs

For the performance plots below, the thermoelectric cooler (TEC) was in a dry package cavity, sealed under nitrogen. The ambient temperature was 27°C. The TEC controller was operated in DC mode (maximum pulse width of a PWM controller) to maintain the cold side (sensor side) temperature at 0°C, while the input signal to the EMCCD registers was 20 mV, the EMCCD gains were set to 20X, and the horizontal clock rate was 20 MHz. For these conditions, the recommended maximum input current (Imax) is 1.1 A, requiring an input voltage (Vmax) of 11.2 V. Lower cold side temperatures may have different optimum operating conditions.
Figure 43. ΔT and Voltage vs. Current
Figure 44.

The plot shown below separately shows the dependence of cooling performance (ΔT) on the thermal resistance of the cooling system.
Figure 45. Maximum ΔT vs. Cooling System Thermal Resistance

The thermoelectric cooler has an on−board thermistor. The current model has ± 3% tolerance and 10 kΩ (Ro) at 25°C (298°K, To). Its performance is shown in the plot below and follows the equation, where T = temperature in °K, over the range of 233°K to 398°K, and RT = thermistor resistance in Ohms.
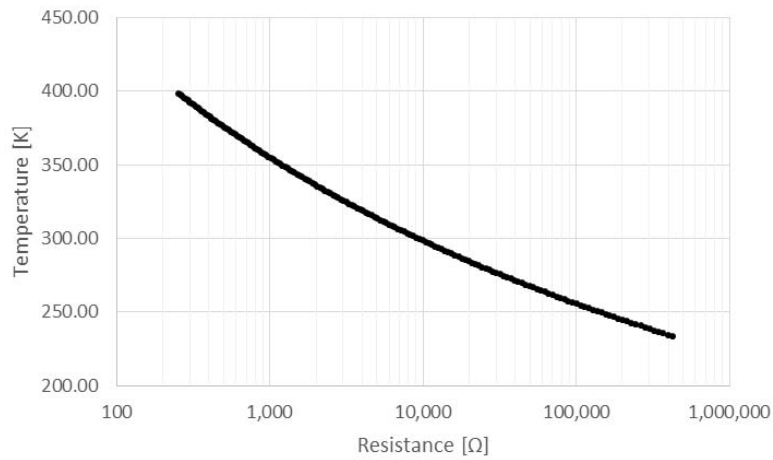

Figure 46. Thermistor Resistance vs. Temperature

$$T = \frac{1}{\left\{ (1.311E-3) + (2.138E-4) * \ln(R_T) + (9.43E-8) * (\ln(R_T))^3 \right\}}$$

STORAGE AND HANDLING

Table 20. STORAGE CONDITIONS

Description	Symbol	Minimum	Maximum	Unit
Temperature (Note 26)	T_{ST}	−55	80	°C
Humidity (Note 27)	RH	5	90	%

26. Long-term exposure toward the maximum temperature will accelerate color filter degradation.
27. T = 25°C. Excessive humidity will degrade Mean Time to Failure (MTTF.)

MAR Glass for PGA with Sealed Cover Glass
NOTES:
1. Dust, Scratch, Inclusion Defect Max: 10 μm (A–Zone)
2. Glass Material is Schott D263T eco
3. Anti–reflection Coatings on both Sides of Substrate to meet the following Minimum Transmission Specifications:

365 nm	Tabs > 50%
400–900 nm	Tabs > 97%
900–1100 nm	Tabs > 85%
900–1100 nm	Tave > 88%

4. Epoxy is B–staged Form (Ref. KSD–248–0109, Spec KSD–241–0009)
5. All Contamination Outside the A–Zone must be Removable with N2 at 40 PSI
6. Edge Chips: X $\leq$ 0.50 mm, Y $\leq$ 0.50 mm, Z $\leq$ 0.48 mm
