## ADC1413S series

Single 14-bit ADC; 65 Msps, 80 Msps, 105 Msps or 125 Msps; serial JESD204A interface
Rev. 03 - 2 July 2012
Product data sheet

## 1. General description

The ADC1413S is a single channel 14-bit Analog-to-Digital Converter (ADC) optimized for high dynamic performance and low power at sample rates up to 125 Msps . Pipelined architecture and output error correction ensure the ADC1413S is accurate enough to guarantee zero missing codes over the entire operating range. Supplied from a 3 V source for analog and a 1.8 V source for the output driver, it outputs data in serial mode via a single differential lane, which complies with the JESD204A standard. The integration of Serial Peripheral Interface (SPI) allows the user to easily configure the ADCs and the serial output modes. The device also includes a programmable full-scale SPI to allow a flexible input voltage range from 1 V ( $p-p$ ) to 2 V ( $p-p$ ).

Excellent dynamic performance is maintained from the baseband to input frequencies of 170 MHz or more, making the ADC1413S ideal for use in communications, imaging, and medical applications.

## 2. Features and benefits

■ SNR, 72.1 dBFS; SFDR, 86 dBc

- Sample rates up to 125 Msps
- Single channel, 14 -bit pipelined ADC core
- $3 \mathrm{~V}, 1.8 \mathrm{~V}$ power supplies
- Flexible input voltage range: 1 V (p-p) to 2 V (p-p)
- serial output
- Compliant with JESD204A serial transmission standard
- Pin compatible with the ADC1613S series, ADC1213S series, and ADC1113S125

■ Input bandwidth, 600 MHz

- Power dissipation, 550 mW at 80 Msps
- SPI register programming
- Duty cycle stabilizer
- High Intermediate Frequency (IF) capability
- Offset binary, two's complement, gray code
- Power-down mode and Sleep mode

■ HVQFN32 package

## 3. Applications

- Portable instrumentation communications
- Spectral analysis ■ Imaging systems
- Ultrasound equipment

## 11. Application information

### 11.1 Analog inputs

### 11.1.1 Input stage description

The analog input of the ADC1413S supports a differential or a single-ended input drive. Optimal performance is achieved using differential inputs with the common-mode input voltage $\left(\mathrm{V}_{\mathrm{I}(\mathrm{cm})}\right)$ on pins INP and INM set to $0.5 \mathrm{~V}_{\text {DDA }}$.

The full-scale analog input voltage range is configurable between $1 \mathrm{~V}(p-p)$ and $2 \mathrm{~V}(p-p)$ via a programmable internal reference (see Section 11.2 and Table 21).

Figure 6 shows the equivalent circuit of the sample-and-hold input stage, including ElectroStatic Discharge (ESD) protection and circuit and package parasitics.

Fig 6. Input sampling circuit
The sample phase occurs when the internal clock (derived from the clock signal on pin CLKP/CLKM) is HIGH. The voltage is then held on the sampling capacitors. When the clock signal goes LOW, the stage enters the hold phase and the voltage information is transmitted to the ADC core.

### 11.1.2 Anti-kickback circuitry

Anti-kickback circuitry (RC filter in Figure 7) is needed to counteract the effects of a charge injection generated by the sampling capacitance.

The RC filter is also used to filter noise from the signal before it reaches the sampling stage. The value of the capacitor should be chosen to maximize noise attenuation without degrading the settling time excessively.

Fig 7. Anti-kickback circuit
The component values are determined by the input frequency and should be selected so as not to affect the input bandwidth.

Table 9. RC coupling versus input frequency, typical values

| Input frequency (MHz) | Resistance $(\Omega)$ | Capacitance $\mathbf{( p F )}$ |
| :---: | :---: | :---: |
| 3 | 25 | 12 |
| 70 | 12 | 8 |
| 170 | 12 | 8 |

### 11.1.3 Transformer

The configuration of the transformer circuit is determined by the input frequency. The configuration shown in Figure 8 would be suitable for a baseband application.

Fig 8. Single transformer configuration

The configuration shown in Figure 9 is recommended for high frequency applications. In both cases, the choice of transformer is a compromise between cost and performance.

Fig 9. Dual transformer configuration

### 11.2 System reference and power management

### 11.2.1 Internal/external reference

The ADC1413S has a stable and accurate built-in internal reference voltage to adjust the ADC full-scale. This reference voltage can be set internally via SPI or with pins VREF and SENSE (see Figure 11 to Figure 14), in 1 dB steps between 0 dB and -6 dB , via SPI control bits INTREF[2:0] (when bit INTREF_EN = logic 1; see Table 21). The equivalent reference circuit is shown in Figure 10. External reference is also possible by providing a voltage on pin VREF as described in Figure 14.

Fig 10. Reference equivalent schematic
Table 10 shows how to choose between the different internal/external modes:
Table 10. Reference modes

| Mode | SPI bit, "Internal reference" | SENSE pin | VREF pin | Full-scale, (V (p-p)) |
| :---: | :---: | :---: | :---: | :---: |
| Internal (Figure 11) | 0 | GND | 330 pF capacitor to GND | 2 |
| Internal (Figure 12) | 0 | VREF pin = SENSE pin and 330 pF capacitor to GND |  | 1 |
| Internal, SPI mode (Figure 13) | 1 | VREF pin = SENSE pin and 330 pF capacitor to GND |  | 1 to 2 |
| External (Figure 14) | 0 | $V_{\text {DDA }}$ | External voltage from 0.5 V to 1 V | 1 to 2 |

Figure 11 to Figure 14 illustrate how to connect the SENSE and VREF pins to select the required reference voltage source.

Fig 12. Internal reference, 1 V (p-p) full-scale

Fig 14. External reference, $1 \mathrm{~V}(\mathrm{p}-\mathrm{p})$ to $2 \mathrm{~V}(\mathrm{p}-\mathrm{p})$ full-scale

### 11.2.2 Programmable full-scale

 The full-scale is programmable between $1 \mathrm{~V}(p-p)$ to $2 \mathrm{~V}(\mathrm{p}-\mathrm{p})$ (see Table 11).Table 11. Reference modes

| INTREF[2:0] | Level | Full-scale (V (p-p)) |
| :--- | :--- | :--- |
| 000 | 0 dB | 2 |
| 001 | -1 dB | 1.78 |
| 010 | -2 dB | 1.59 |
| 011 | -3 dB | 1.42 |
| 100 | -4 dB | 1.26 |
| 101 | -5 dB | 1.12 |
| 110 | -6 dB | 1 |
| 111 | not used | $x$ |

### 11.2.3 Common-mode output voltage $\left(\mathrm{V}_{\mathrm{O}(\mathrm{cm})}\right)$

An $0.1 \mu \mathrm{~F}$ filter capacitor should be connected between pin VCM and ground to ensure a low-noise common-mode output voltage. When AC-coupled, these pins can be used to set the common-mode reference for the analog inputs, for instance via a transformer middle point.

Fig 15. Reference equivalent schematic

### 11.2.4 Biasing

The common-mode input voltage $\left(\mathrm{V}_{\mathrm{I}(\mathrm{cm})}\right)$ on pins INP and INM should be set externally to $0.5 \mathrm{~V}_{\mathrm{DDA}}$ for optimal performance and should always be between 0.9 V and 2 V .

### 11.3 Clock input

### 11.3.1 Drive modes

The ADC1413S can be driven differentially (LVPECL). It can also be driven by a single-ended LVCMOS signal connected to pin CLKP (CLKM should be connected to ground via a capacitor).

### 11.3.2 Equivalent input circuit

The equivalent circuit of the input clock buffer is shown in Figure 18. The common-mode voltage of the differential input stage is set via internal $5 \mathrm{k} \Omega$ resistors.

$005 a a a 081$
$\mathrm{V}_{\mathrm{cm}(\mathrm{ck})}=$ common-mode voltage of the differential input stage.
Fig 18. Equivalent input circuit

Single-ended or differential clock inputs can be selected via the SPI (see Table 20). If single-ended is selected, the input pin (CLKM or CLKP) is selected via control bit SE_SEL.

If single-ended is implemented without setting bit SE_SEL accordingly, the unused pin should be connected to ground via a capacitor.

### 11.3.3 Duty cycle stabilizer

The duty cycle stabilizer can improve the overall performance of the ADC by compensating the input clock signal duty cycle. When the duty cycle stabilizer is active (bit DCS_EN = logic 1; see Table 20), the circuit can handle signals with duty cycles of between $30 \%$ and $70 \%$ (typical). When the duty cycle stabilizer is disabled
(DCS_EN = logic 0), the input clock signal should have a duty cycle of between $45 \%$ and 55 \%.

Table 12. Duty cycle stabilizer

| bit DCS_EN | Description |
| :--- | :--- |
| 0 | duty cycle stabilizer disable |
| 1 | duty cycle stabilizer enable |

### 11.3.4 Clock input divider

The ADC1413S contains an input clock divider that divides the incoming clock by a factor of 2 (when bit CLKDIV2_SEL = logic 1; see Table 20). This feature allows the user to deliver a higher clock frequency with better jitter performance, leading to a better SNR result once acquisition has been performed.

### 11.4 Digital outputs

### 11.4.1 Serial output equivalent circuit

The JESD204A standard specifies that if the receiver and the transmitter are DC-coupled both must be fed from the same supply.

Fig 19. CML output connection to the receiver (DC-coupling)
The output should be terminated when $100 \Omega$ (typical) is reached at the receiver side.

Fig 20. CML output connection to the receiver (AC-coupling)

### 11.5 JESD204A serializer

For more information about the JESD204A standard refer to the JEDEC web site.

### 11.5.1 Digital JESD204A formatter

The block placed after the ADC cores is used to implement all functions of the JESD204A standard. This ensures signal integrity and guarantees the clock and the data recovery at the receiver side.

The block is highly parameterized and can be configured in various ways depending on the sampling frequency and the number of lanes used.

### 11.6 Serial Peripheral Interface (SPI)

### 11.6.1 Register description

The ADC1413S serial interface is a synchronous serial communications port allowing easy interfacing with many industry microprocessors. It provides access to the registers that control the operation of the chip in both read and write modes.

This interface is configured as a 3-wire type (SDIO as bidirectional pin).
Pin SCLK acts as the serial clock and pin $\overline{\mathrm{CS}}$ acts as the serial chip select.
Each read/write operation is sequenced by the $\overline{C S}$ signal and enabled by a LOW level to to drive the chip with N bytes, depending on the content of the instruction byte (see Table 14).

Table 14. Instruction bytes for the SPI

|  | MSB |  |  |  |  |  | LSB |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Description | R/W ${ }^{[1]}$ | W1 | W0 | A12 | A11 | A10 | A9 | A8 |
|  | A7 | A6 | A5 | A4 | A3 | A2 | A1 | A0 |

[1] R/W indicates whether a read or write transfer occurs after the instruction byte.

Table 15. Read or Write mode access description

| $R / W^{[1]}$ | Description |
| :--- | :--- |
| 0 | Write mode operation |
| 1 | Read mode operation |

[1] Bits W1 and W0 indicate the number of bytes transferred.

Table 16. Number of bytes to be transferred

| W1 | W0 | Number of bytes transferred |
| :--- | :--- | :--- |
| 0 | 0 | 1 byte |
| 0 | 1 | 2 bytes |
| 1 | 0 | 3 bytes |
| 1 | 1 | 4 or more bytes |

Bits A12 to A0 indicate the address of the register being accessed. In the case of a multiple byte transfer, this address is the first register to be accessed. An address counter is incremented to access subsequent addresses.

The steps involved in a data transfer are as follows:

1. The falling edge on pin $\overline{\mathrm{CS}}$ in combination with a rising edge on pin SCLK determine the start of communications.
2. The first phase is the transfer of the 2-byte instruction.
3. The second phase is the transfer of the data which can be vary in length but is always a multiple of 8 bits. The MSB is always sent first (for instruction and data bytes).
4. A rising edge on pin $\overline{\mathrm{CS}}$ indicates the end of data transmission.

| :---: | :---: | :---: | :---: | :---: |
| 7 | - | - | 0 | not used |
| 6 | SCR_IN_MODE | R/W |  | defines the input type for scrambler and 8-bit/10-bit units: |
|  |  |  | 0 (reset) | (normal mode) = Input of the scrambler and 8-bit/10-bit units is the output of the frame assembly unit. |
|  |  |  | 1 | input of the scrambler and 8-bit/10-bit units is the PRSB generator (PRBS type is defined with "PRBS_TYPE[1:0]" (Ser_PRBS_ctrl register) |
| 5 to 4 | LANE_MODE[1:0] | R/W |  | defines output type of Lane output unit: |
|  |  |  | 00 (reset) | normal mode: Lane output is the 8-bit/10-bit output unit |
|  |  |  | 01 | constant mode: Lane output is set to a constant ( $0 \times 0$ ) |
|  |  |  | 10 | toggle mode: Lane output is toggling between $0 \times 0$ and $0 \times 1$ |
|  |  |  | 11 | PRBS mode: Lane output is the PRBS generator (PRBS type is defined with "PRBS_TYPE[1:0]" (Ser_PRBS_ctrl register) |

| Bit | Symbol | Access | Value | Description |
| :--- | :--- | :--- | :--- | :--- |
| 2 | LANE_POL | R/W |  | defines lane polarity: |
|  |  | $\mathbf{0}$ | lane polarity is normal |  |
|  |  | 1 | lane polarity is inverted |  |
| 1 | RESERVED | R/W | $\mathbf{0}$ | reserved |
| 0 | Lane_PD | R/W |  | lane power-down control: |
|  |  | $\mathbf{0}$ | lane is operational |  |
|  |  | 1 | lane is in Power-down mode |  |

Default values are highlighted.

| Bit | Symbol | Access | Value | Description |
| :---: | :---: | :---: | :---: | :---: |
| 7 to 6 | - | - | 00 | not used |
| 5 to 4 | ADC_MODE[1:0] | R/W |  | defines input type of JESD204A unit |
|  |  |  | 00 (reset) | ADC output is connected to the JESD204A input |
|  |  |  | 01 | not used |
|  |  |  | 10 | JESD204A input is fed with a dummy constant, set to: OTR $=0$ and ADC[13:0] = "10011011101010" |
|  |  |  | 11 | JESD204A is fed with a PRBS generator (PRBS type is defined with "PRBS_TYPE[1:0]" (Ser_PRBS_ctrl register) |
| 3 to 1 | - | - | 000 | not used |
| 0 | ADC_PD | R/W |  | ADC power-down control: |
|  |  |  | 0 | ADC is operational |
|  |  |  | 1 | ADC is in Power-down mode |

[^0]:    [1] an "*" in the Access column means that this register is subject to control access conditions in Write mode.
    [2] an "*" in the Default column replaces a bit of which the value depends on the binary level of external pins (e.g. CFG[3:0], Swing[1:0], Scrambler).
