

## FEATURES

- Operates from +1.7 V to  $\pm 18$  V**
- Low supply current: 15  $\mu$ A/amplifier**
- Low offset voltage: 100  $\mu$ V maximum**
- Outputs sink and source:  $\pm 8$  mA**
- No phase reversal**
- Single- or dual-supply operation**
- High open-loop gain: 600 V/mV**
- Unity-gain stable**

## APPLICATIONS

- Digital scales**
- Strain gages**
- Portable medical equipment**
- Battery-powered instrumentation**
- Temperature transducer amplifier**

## GENERAL DESCRIPTION

The **OP193/OP293** are single-supply operational amplifiers that feature a combination of high precision, low supply current, and the ability to operate at low voltages. For high performance in single-supply systems, the input and output ranges include ground, and the outputs swing from the negative rail to within 600 mV of the positive supply. For low voltage operation, the **OP193/OP293** can operate down to +1.7 V or  $\pm 0.85$  V.

The combination of high accuracy and low power operation make the **OP193/OP293** useful for battery-powered equipment. The part's low current drain and low voltage operation allow it to continue performing long after other amplifiers have ceased functioning either because of battery drain or headroom.

The **OP193/OP293** are specified for single +2 V through dual  $\pm 15$  V operation over the extended ( $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$ ) temperature range. They are available in SOIC surface-mount packages.

## ABSOLUTE MAXIMUM RATINGS

Table 5.

Parameter	Rating
Supply Voltage <sup>1</sup>	±18 V
Input Voltage <sup>1</sup>	±18 V
Differential Input Voltage <sup>1</sup>	±18 V
Output Short-Circuit Duration to GND	Indefinite
Storage Temperature Range	−65°C to +150°C
Operating Temperature Range	−40°C to +125°C
Junction Temperature Range	−65°C to +150°C
Lead Temperature (Soldering, 60 sec)	300°C

<sup>1</sup> For supply voltages less than ±18 V, the input voltage is limited to the supply voltage.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

### THERMAL RESISTANCE

$\theta_{JA}$  is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 6. Thermal Resistance

Package Type	$\theta_{JA}$ <sup>1</sup>	$\theta_{JC}$	Unit
8-Lead SOIC_N (S)	158	43	°C/W

<sup>1</sup>  $\theta_{JA}$  is specified for the worst-case conditions.  $\theta_{JA}$  is specified for a device soldered in a circuit board for the SOIC package.

### ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## FUNCTIONAL DESCRIPTION

The OP193/OP293 operational amplifiers are single-supply, micropower, precision amplifiers whose input and output ranges both include ground. Input offset voltage ( $V_{OS}$ ) is only 100  $\mu$ V maximum, while the output delivers  $\pm 5$  mA to a load. Supply current is only 15  $\mu$ A.

A simplified schematic of the input stage is shown in Figure 26. The input transistors, Q1 and Q2, are PNP devices, which permit the inputs to operate down to ground potential. The input transistors have resistors in series with the base terminals to protect the junctions from overvoltage conditions. The second stage is an NPN cascode that is buffered by an emitter follower before driving the final PNP gain stage.

The OP193 includes connections to taps on the input load resistors, which can be used to null the input offset voltage,  $V_{OS}$ . The OP293 have two additional transistors, Q7 and Q8. The behavior of these transistors is discussed in the Output Phase Reversal— and Output Phase Reversal— sections.

The output stage, shown in Figure 25, is a noninverting NPN totem-pole configuration. Current is sourced to the load by Emitter Follower Q1, while Q2 provides current sink capability. When Q2 saturates, the output is pulled to within 5 mV of ground without an external pull-down resistor. The totem-pole output stage supplies a minimum of 5 mA to an external load, even when operating from a single 3.0 V power supply.

Figure 25. OP193/OP293 Equivalent Output Circuit

By operating as an emitter follower, Q1 offers a high impedance load to the final PNP collector of the input stage. Base drive to Q2 is derived by monitoring Q1's collector current. Transistor Q5 tracks the collector current of Q1. When Q1 is on, Q5 keeps Q4 off, and Current Source I1 keeps Q2 turned off. When Q1 is driven to cutoff (that is, the output must move toward V-), Q5 allows Q4 to turn on. Q4's collector current then provides the base drive for Q3 and Q2, and the output low voltage swing is set by Q2's  $V_{CE,SAT}$ , which is about 5 mV.

### DRIVING CAPACITIVE LOADS

The OP193/OP293 amplifiers are unconditionally stable with capacitive loads less than 200 pF. However, the small signal, unity-gain overshoot improves if a resistive load is added. For example, transient overshoot is 20% when driving a 1000 pF, 10 k $\Omega$  load. When driving large capacitive loads in unity-gain configurations, an in-the-loop compensation technique is recommended, as illustrated in Figure 30.

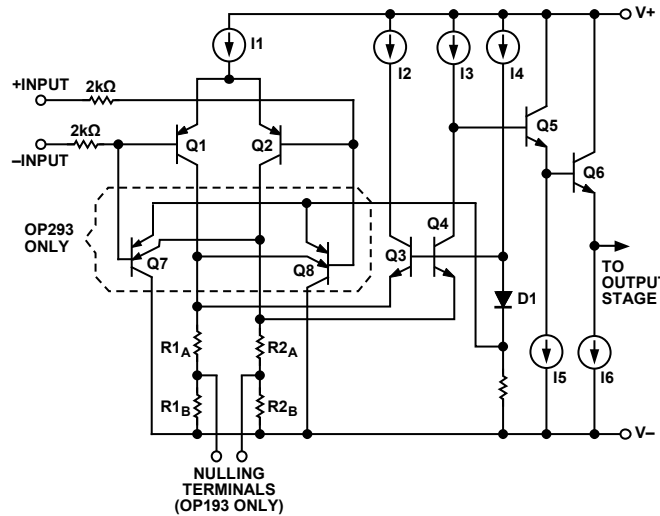

Figure 26. OP193/OP293 Equivalent Input Circuit

**INPUT OVERVOLTAGE PROTECTION**

As previously mentioned, the OP193/OP293 op amps use a PNP input stage with protection resistors in series with the inverting and noninverting inputs. The high breakdown of the PNP transistors, coupled with the protection resistors, provides a large amount of input protection from overvoltage conditions. The inputs can therefore be taken 20 V beyond either supply without damaging the amplifier.

**OUTPUT PHASE REVERSAL—OP193**

The OP193’s input PNP collector-base junction can be forward-biased if the inputs are brought more than one diode drop (0.7 V) below ground. When this happens to the noninverting input, Q4 of the cascode stage turns on and the output goes high. If the positive input signal can go below ground, phase reversal can be prevented by clamping the input to the negative supply (that is, GND) with a diode. The reverse leakage of the diode does add to the input bias current of the amplifier. If input bias current is not critical, a 1N914 diode adds less than 10 nA of leakage. However, its leakage current doubles for every 10°C increase in ambient temperature. For critical applications, the collector-base junction of a 2N3906 transistor adds only about 10 pA of additional bias current. To limit the current through the diode under fault conditions, a 1 kΩ resistor is recommended in series with the input. (The OP193’s internal current limiting resistors do not protect the external diode.)

**OUTPUT PHASE REVERSAL—OP293**

The OP293 includes two lateral PNP transistors, Q7 and Q8, to protect against phase reversal. If an input is brought more than one diode drop ( $\approx 0.7$  V) below ground, Q7 and Q8 combine to level shift the entire cascode stage, including the bias to Q3 and Q4, simultaneously. In this case, Q4 does not saturate and the output remains low.

The OP293 does not exhibit output phase reversal for inputs up to  $-5$  V below  $V-$  at  $+25^\circ\text{C}$ . The phase reversal limit at  $+125^\circ\text{C}$  is about  $-3$  V. If the inputs can be driven below these levels, an external clamp diode, as discussed in the previous section, should be added.

**BATTERY-POWERED APPLICATIONS**

OP193/OP293 series op amps can be operated on a minimum supply voltage of 1.7 V, and draw only 13  $\mu\text{A}$  of supply current per amplifier from a 2.0 V supply. In many battery-powered circuits, OP193/OP293 devices can be continuously operated for thousands of hours before requiring battery replacement, thus reducing equipment downtime and operating cost.

High performance portable equipment and instruments frequently use lithium cells because of their long shelf life, light weight, and high energy density relative to older primary cells. Most lithium cells have a nominal output voltage of 3 V and are noted for a flat discharge characteristic. The low supply voltage requirement of the OP193/OP293, combined with the flat discharge characteristic of the lithium cell, indicates that the

OP193/OP293 can be operated over the entire useful life of the cell. Figure 27 shows the typical discharge characteristic of a 1 Ah lithium cell powering the OP193 and OP293, with each amplifier, in turn, driving 2.1 V into a 100 kΩ load.

Figure 27. Lithium Sulfur Dioxide Cell Discharge Characteristic with OP193/OP293 and 100 kΩ Loads Input Offset Voltage Nulling

The OP193 provides two offset nulling terminals that can be used to adjust the OP193’s internal  $V_{os}$ . In general, operational amplifier terminals should never be used to adjust system offset voltages. The offset nulling circuit of Figure 28 provides about  $\pm 7$  mV of offset adjustment range. A 100 kΩ resistor placed in series with the wiper arm of the offset null potentiometer, as shown in Figure 29, reduces the offset adjustment range to 400  $\mu\text{V}$  and is recommended for applications requiring high null resolution. Offset nulling does not adversely affect  $\text{TCV}_{os}$  performance, providing that the trimming potentiometer temperature coefficient does not exceed  $\pm 100$  ppm/ $^\circ\text{C}$ .

Figure 28. Offset Nulling Circuit

Figure 29. High Resolution Offset Nulling Circuit

**A MICROPOWER FALSE-GROUND GENERATOR**

Some single-supply circuits work best when inputs are biased above ground, typically at 1/2 of the supply voltage. In these cases, a false ground can be created by using a voltage divider buffered by an amplifier. One such circuit is shown in Figure 30.

This circuit generates a false-ground reference at 1/2 of the supply voltage, while drawing only about 27 μA from a 5 V supply. The circuit includes compensation to allow for a 1 μF bypass capacitor at the false-ground output. The benefit of a large capacitor is that not only does the false ground present a very low dc resistance to the load, but its ac impedance is low as well. The OP193 can both sink and source more than 5 mA, which improves recovery time from transients in the load current.

Figure 30. A Micropower False-Ground Generator

**A BATTERY-POWERED VOLTAGE REFERENCE**

The circuit of Figure 31 is a battery-powered voltage reference that draws only 17 μA of supply current. At this level, two AA alkaline cells can power this reference for more than 18 months. At an output voltage of 1.23 V at 25°C, drift of the reference is only 5.5 μV/°C over the industrial temperature range. Load regulation is 85 μV/mA with line regulation at 120 μV/V.

Design of the reference is based on the Brokaw band gap core technique. Scaling of Resistor R1 and Resistor R2 produces unequal currents in Q1 and Q2. The resulting ΔV<sub>BE</sub> across R3 creates a temperature-proportional voltage (PTAT), which, in turn, produces a larger temperature-proportional voltage across R4 and R5, V1. The temperature coefficient of V1 cancels (first order) the complementary to absolute temperature (CTAT) coefficient of V<sub>BE1</sub>. When adjusted to 1.23 V at 25°C, output voltage temperature coefficient is at a minimum. Band gap references can have start-up problems. With no current in R1 and R2, the OP193 is beyond its positive input range limit and has an undefined output state. Shorting Pin 5 (an offset adjust pin) to ground forces the output high under these circumstances and ensures reliable startup without significantly degrading the OP193's offset drift.

Figure 31. A Battery-Powered Voltage Reference

**A SINGLE-SUPPLY CURRENT MONITOR**

Current monitoring essentially consists of amplifying the voltage drop across a resistor placed in series with the current to be measured. The difficulty is that only small voltage drops can be tolerated, and with low precision op amps, this greatly limits the overall resolution. The single-supply current monitor of Figure 32 has a resolution of 10 μA and is capable of monitoring 30 mA of current. This range can be adjusted by changing the current sense resistor, R1. When measuring total system current, it may be necessary to include the supply current of the current monitor, which bypasses the current sense resistor, in the final result. This current can be measured and calibrated (together with the residual offset) by adjustment of the offset trim potentiometer, R2. This produces a deliberate temperature dependent offset. However, the supply current of the OP193 is also proportional to temperature, and the two effects tend to track. Voltage developed at the noninverting input and amplified by (1 + R4/R5) appears at V<sub>OUT</sub>.

Figure 32. Single-Supply Current Monitor

**A SINGLE-SUPPLY INSTRUMENTATION AMPLIFIER**

Designing a true single-supply instrumentation amplifier with zero-input and zero-output operation requires special care. The traditional configuration, shown in Figure 33, depends upon Amplifier A1's output being at 0 V when the applied common-mode input voltage is at 0 V. Any error at the output is multiplied by the gain of A2. In addition, current flows through Resistor R3 as A2's output voltage increases. A1's output must remain at 0 V while sinking the current through R3, or a gain error results. With a maximum output voltage of 4 V, the current through R3 is only 2 μA, but this still produces an appreciable error.

Figure 33. A Conventional Instrumentation Amplifier

One solution to this problem is to use a pull-down resistor. For example, if R3 = 20 kΩ, then the pull-down resistor must be less than 400 Ω. However, the pull-down resistor appears as a fixed load when a common-mode voltage is applied. With a 4 V common-mode voltage, the additional load current is 10 mA, which is unacceptable in a low power application.

Figure 34 shows a better solution. A1's sink current is provided by a pair of N-channel FET transistors, configured as a current mirror. With the values shown, the sink current of Q2 is about 340 μA. Thus, with a common-mode voltage of 4 V, the additional load current is limited to 340 μA vs. 10 mA with a 400 Ω resistor.

Figure 34. An Improved Single-Supply, 0 VIN, 0 VOUT Instrumentation Amplifier

**A LOW POWER, TEMPERATURE TO 4 mA TO 20 mA TRANSMITTER**

A simple temperature to 4 mA to 20 mA transmitter is shown in Figure 35. After calibration, this transmitter is accurate to ±0.5°C over the -50°C to +150°C temperature range. The transmitter operates from 8 V to 40 V with supply rejection better than 3 ppm/V. One half of the OP293 is used to buffer the TEMP pin, and the other half regulates the output current to satisfy the current summation at its noninverting input.

$$I_{OUT} + \frac{V_{TEMP} \times (R6 + R7)}{R2 \times R10} - V_{SET} \left( \frac{R2 + R6 + R7}{R2 \times R10} \right)$$

The change in output current with temperature is the derivative of the following transfer function:

$$\frac{\Delta I_{OUT}}{\Delta T} = \frac{\Delta V_{TEMP} \cdot (R6 + R7)}{R2 \times R10}$$

NOTES  
1. ALL RESISTORS 1/4 W, 5% UNLESS OTHERWISE NOTED.

Figure 35. Temperature to 4 mA to 20 mA Transmitter

From the formulas, it can be seen that if the span trim is adjusted before the zero trim, the two trims are not interactive, which greatly simplifies the calibration procedure.

Calibration of the transmitter is simple. First, the slope of the output current vs. temperature is calibrated by adjusting the span trim, R7. A couple of iterations may be required to be sure the slope is correct.

When the span trim has been adjusted, the zero trim can be made. Adjusting the zero trim does not affect the gain.

The zero trim can be set at any known temperature by adjusting R5 until the output current equals:

$$I_{OUT} = \left( \frac{\Delta I_{FS}}{\Delta T_{OPERATING}} \right) (T_{AMBIENT} - T_{MIN}) + 4 \text{ mA}$$

Table 7 shows the values of R6 required for various temperature ranges.

Table 7. R6 Values vs. Temperature

Temp Range	R6
0°C to 70°C	10 kΩ
-40°C to +85°C	6.2 kΩ
-55°C to +150°C	3 kΩ

### A MICROPOWER VOLTAGE CONTROLLED OSCILLATOR

The OP293 CMOS analog switch forms the precision VCO of Figure 36. This circuit provides triangle and square wave outputs and draws only 50 μA from a single 5 V supply. A1 acts as an integrator; S1 switches the charging current symmetrically to yield positive and negative ramps. The integrator is bounded by A2, which acts as a Schmitt trigger with a precise hysteresis of 1.67 V, set by Resistor R5, Resistor R6, and Resistor R7, and associated CMOS switches. The resulting output of A1 is a triangle wave with upper and lower levels of 3.33 V and 1.67 V. The output of A2 is a square wave with almost rail-to-rail swing. With the components shown, frequency of operation is given by the equation:

$$f_{OUT} = V_{CONTROL} \text{ V} \times 10 \text{ Hz/V}$$

However, the frequency can easily be changed by varying C1. The circuit operates well up to 500 Hz.
