## FEATURES

Low offset voltage: $\mathbf{1 0 0} \boldsymbol{\mu V}$ max Low offset voltage drift: $2 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}$ max
Low input bias current: $\mathbf{7 0 0}$ pA max
Low noise: $\mathbf{8 n V / \sqrt { H z }}$
High common-mode rejection: 118 dB min
Wide operating temperature: $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
No phase reversal

## GENERAL DESCRIPTION

The AD8698 is a high precision, rail-to-rail output, low noise, low input bias current operational amplifier. Offset voltage is a respectable $100 \mu \mathrm{~V}$ max and drift over temperature is below $2 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}$, eliminating the need for manual offset trimming. The AD8698 is ideal for high impedance sensors, minimizing offset errors due to input bias and offset currents.

The rail-to-rail output maximizes dynamic range in a variety of applications, such as photodiode amplifiers, DAC I/V amplifiers, filters, and ADC input amplifiers.

The AD8698 dual amplifiers are offered in 8-lead MSOP and narrow 8-lead SOIC packages. The MSOP version is available in tape and reel only.

Rev. 0

| section of this specification is not implied. Exposure to absolute |  |
| maximum rating conditions for extended periods may affect |  |
| device reliability. |  |

## THERMAL RESISTANCE

$\theta_{\mathrm{JA}}$ is specified for the worst-case conditions, i.e., $\theta_{\mathrm{JA}}$ is specified for devices soldered in circuit boards for surface-mount packages.

Table 4. Thermal Resistance

| Package Type | $\theta_{\mathrm{JA}}$ | $\theta_{\mathbf{\prime c}}$ | Unit |
| :--- | :--- | :--- | :--- |
| MSOP-8 (RM) | 210 | 45 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| SOIC-8 (R) | 158 | 43 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 1000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## AD8698

## APPLICATIONS

## INPUT OVERVOLTAGE PROTECTION

The AD8698 has internal protective circuitry which allows voltages at either input to exceed the supply voltage. However, if voltages applied at either input exceed the supply voltage by more than 2 V , it is recommended to use a resistor in series with the inputs to limit the input current and prevent damaging the device.

The value of the resistor can be calculated from the following formula:

$$
\frac{V_{I N}-V_{S}}{R_{S}+500} \leq 5 \mathrm{~mA}
$$

## DRIVING CAPACITIVE LOADS

The AD8698 is stable even when driving heavy capacitive loads in any configuration. Although the AD8698 will safely drive capacitive loads well over 10 nF , it is recommended to use external compensation should the amplifier be subjected to driving a load exceeding 50 nF . This is particularly important in positive unity gain configurations, the worst case for stability. Figure 49 shows the output of the AD8698 with a 68 nF load in response to a 400 mV signal at its positive input; the overshoot is less than $25 \%$ without any external compensation. Using a simple "snubber" network reduces the overshoot to less than $10 \%$ as shown in Figure 50.

Figure 52 shows the unity gain bandwidth as a function of load capacitance.

## INSTRUMENTATION AMPLIFIER

Instrumentation amplifiers are used in applications requiring precision, accuracy, and high CMRR. One popular application is signal conditioning in process control, test automation, and measurement instrumentation, where the amplifier is used to amplify small signals.

The triple op amp implementation uses the AD8698 at the front end with the OP184 for optimum accuracy.

The circuit in Figure 53 enjoys a high overall gain, excellent dc performance, high CMRR, as well as the benefit of an output that swings to the supplies.

The CMRR of the in-amp will be limited by the choice of resistor tolerance. R5 is an optional potentiometer that can be used to calibrate the circuit for maximum gain. R7 can be trimmed for optimum CMRR.

The output voltage is given by:
$V_{O}=V_{I N}\left(1+\frac{2 R 3}{R 4}\right)\left(\frac{R 2}{R 1}\right)$

Figure 53. Three Op Amp In-Amp

## COMPOSITE AMPLIFIER

The dc accuracy of the AD8698 and the ac performance of the OP184 are combined in the circuit shown in Figure 54. The composite amplifier provides a higher bandwidth, a lower offset voltage, and a higher loop, thereby reducing the gain error substantially.

The circuit shown exhibits a total output rms noise of less than $500 \mu \mathrm{~V}$, corresponding to less than 3 mV of peak-to-peak noise over approximately a 3 MHz bandwidth. Cf is used to minimize peaking.

The circuit has an inverting gain of 10. In applications with higher closed-loop gains, Cf is necessary to maintain a sufficient phase margin and ensure stability. This results in a narrower closed-loop bandwidth.

Figure 54. Composite Amplifier Circuit

## AD8698

## LOW NOISE APPLICATIONS

In some applications, it is critical to minimize the noise, and although the AD8698 has a low noise of typically $8 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$ at 1 kHz , paralleling the two amplifiers within the same package reduces the total noise referred to the input to approximately $5.5 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$. This simple technique is depicted in Figure 55.

Figure 55. Paralleling Amplifiers

## DRIVING ADCs

The AD8698 can drive extremely heavy capacitive loads without any compensation. Sometimes capacitors are placed at the output of the amplifier to absorb transient currents while the op amp is interfaced with the ADC. Most op amps need a small resistor with the output to isolate the load capacitance.

This results in a loss of bandwidth and slows the amplifier down substantially. However, the AD8698 maintains a unity gain bandwidth of 1 MHz with loads of up to 1 nF , as shown in Figure 52.

## USING THE AD8698 IN ACTIVE FILTER DESIGNS

The AD8698 is recommended for unity gain filter designs with a corner frequency of up to 100 kHz , one tenth of the op amp's unity gain bandwidth.

If a higher gain is desired, the corner frequency should be chosen accordingly. For example, if the amplifier is configured with a gain of 10 , the corner frequency of the filter should not be more than 10 kHz .

An example of an active filter is the Sallen Key. This topology gives the user the flexibility of implementing a low-pass or a high-pass filter by simply interchanging the resistors and the capacitors.

In the high-pass filter of Figure 56, the damping factor Q is set to $1 / \sqrt{ } 2$ for a maximally flat response (Butterworth).

The gain is unity and the bandwidth is 10 kHz with the values shown.

Figure 56. Two Pole High-Pass Filter

Figure 57. Two Pole Low-Pass Filter
The circuit of Figure 57 has a bandwidth of 10 kHz and a maximally flat response. In this case, the damping factor is controlled by the ratio of the capacitors and the gain is unity.
