#### GENERAL DESCRIPTION

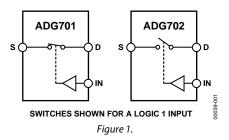

The ADG701/ADG702 are monolithic CMOS SPST switches. These switches are designed on an advanced submicron process that provides low power dissipation yet high switching speed, low on resistance, and low leakage currents. In addition, -3 dB bandwidths of greater than 200 MHz can be achieved.

The ADG701/ADG702 can operate from a single 1.8 V to 5.5 V supply, making it ideal for use in battery-powered instruments and with the new generation of DACs and ADCs from Analog Devices, Inc.

Figure 1 shows that with a logic input of 1, the switch of the ADG701 is closed and that of the ADG702 is open. Each switch conducts equally well in both directions when on.

The ADG701/ADG702 are available in 5-lead SOT-23, 6-lead SOT-23, and 8-lead MSOP packages.

#### PRODUCT HIGHLIGHTS

- 1. 1.8 V to 5.5 V Single-Supply Operation. The ADG701/ADG702 offer high performance, including low on resistance and fast switching times, and are fully specified and guaranteed with 3 V and 5 V supply rails.
- 2. Very Low  $R_{ON}$  (3  $\Omega$  Maximum at 5 V, 5  $\Omega$  Maximum at 3 V). At 1.8 V operation,  $R_{ON}$  is typically 40  $\Omega$  over the tempera-
- On Resistance Flatness  $R_{FLAT(ON)}$  (1  $\Omega$  Maximum).
- −3 dB Bandwidth > 200 MHz.
- Low Power Dissipation. CMOS construction ensures low power dissipation.
- Fast ton/toff.

 $<sup>^{\</sup>rm 1}$  Overvoltages at IN, S, or D are clamped by internal diodes. Current should be limited to the maximum ratings given.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Only one absolute maximum rating may be applied at any one time.

### **ESD CAUTION**

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

### APPLICATIONS INFORMATION

The ADG701/ADG702 belong to the Analog Devices family of CMOS switches. This series of general-purpose switches has improved switching times, lower on resistance, higher bandwidth, low power consumption, and low leakage currents.

### **ADG701/ADG702 SUPPLY VOLTAGES**

Functionality of the ADG701/ADG702 extends from 1.8 V to 5.5 V single supply, making the parts ideal for battery-powered instruments, where power efficiency and performance are important design parameters.

It is important to note that the supply voltage affects the input signal range, on resistance, and switching times of the part. The effects of the power supplies can be clearly seen in the Typical Performance Characteristics and the Specifications sections.

For  $V_{DD}$  = 1.8 V operation,  $R_{ON}$  is typically 40  $\Omega$  over the temperature range.

### **BANDWIDTH**

Figure 18 illustrates the parasitic components that affect the ac performance of CMOS switches (a box surrounds the switch). Additional external capacitances further degrade performance by affecting feedthrough, crosstalk, and system bandwidth.

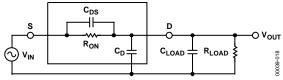

Figure 18. Switch Represented by Equivalent Parasitic Components

The transfer function that describes the equivalent diagram of the switch (see Figure 18) is of the form (A)s, shown in the following equation:

$$A(s) = R_T \left[ \frac{s(R_{ON}C_{DS}) + 1}{s(R_{ON}C_TR_T) + 1} \right]$$

where  $C_T = C_{LOAD} + C_D + C_{DS}$ .

The signal transfer characteristic is dependent on the switch channel capacitance,  $C_{DS}$ . This capacitance creates a frequency zero in the numerator of the transfer function A(s). Because the switch on resistance is small, this zero usually occurs at high frequencies. The bandwidth is a function of the switch output capacitance combined with  $C_{DS}$  and the load capacitance. The frequency pole corresponding to these capacitances appears in the denominator of A(s).

The dominant effect of the output capacitance,  $C_D$ , causes the pole breakpoint frequency to occur first. To maximize bandwidth, a switch must have a low input and output capacitance and low on resistance. The on response vs. frequency for the ADG701/ADG702 can be seen in Figure 10.

### **OFF ISOLATION**

Off isolation is a measure of the input signal coupled through an off switch to the switch output. The capacitance,  $C_{DS}$ , couples the input signal to the output load when the switch is off, as shown in Figure 19.

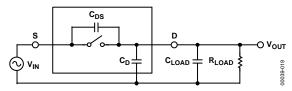

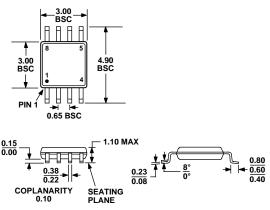

Figure 19. Off Isolation Is Affected by External Load Resistance and Capacitance

The larger the value of  $C_{DS}$ , the larger the values of feedthrough produced. Figure 9 illustrates the drop in off isolation as a function of frequency. From dc to roughly 1 MHz, the switch shows better than -75 dB isolation. Up to frequencies of 10 MHz, the off isolation remains better than -55 dB. As the frequency increases, more of the input signal is coupled through to the output. Off isolation can be maximized by choosing a switch with the smallest  $C_{DS}$  possible. The values of load resistance and capacitance also affect off isolation, because they contribute to the coefficients of the poles and zeros in the transfer function of the switch when open.

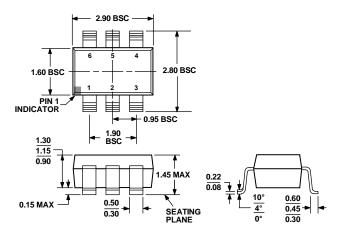

$$A(s) = R_T \left[ \frac{s(R_{LOAD}C_{DS}) + 1}{s(R_{LOAD})(C_T) + 1} \right]$$
