## features

\author{

- Dual 2A and One 500mA, 50V Internal Power Switch Channels
}
- 2A Primary Channels Can Be Buck, Boost, SEPIC, ZETA, Flyback or Inverting DC/DC Converter
- 500mA Skyhook Channel Efficiently Generates Boosted Input Voltage
- Wide Input Voltage Range of 2.6V to 50V
- UVLO and OVLO Programmable on OV/UV Pin
- Soft-Start Programmable for Each Channel
- Fixed Frequency PWM (Set by RT Pin or Synchronized to External Clock)
- Anti-Phase Switching Reduces Input Ripple
- 20-Lead TSSOP and 28-Lead QFN Packages

## APPLICATIONS

- Dual Rail Power for Signal Chain.
- Buck/Buck, Buck/Boost, Boost/Boost, Boost/Invert, Invert/Invert, Buck/Invert

## DESCRIPTIO

The LT ${ }^{\circledR} 8471$ is a dual PWM DC/DC converter containing two internal $2 \mathrm{~A}, 50 \mathrm{~V}$ switches and an additional 500 mA switch to facilitate step-down and inverting conversion. Each 2A channel can be independently configured as a buck, boost, SEPIC, flyback or inverting converter. Capable of generating positive and negative outputs from a single input rail, the LT8471 is ideal for many local power supply designs.

The LT8471 has an adjustable oscillator, set by a resistor placed from the RT pin to ground. Additionally, the LT8471 can be synchronized to an external clock. The free running or synchronized switching frequency range of the part can be set between 100 kHz and 2 MHz .

Additional features such as frequency foldback, soft-start, and power good are integrated. The LT8471 is available in 20-lead TSSOP and 28 -Lead ( $4 \mathrm{~mm} \times 5 \mathrm{~mm}$ ) QFN packages.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: The LT8471E is guaranteed to meet performance specifications from $0^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ junction temperature. Specifications over the $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ operating junction temperature range are assured by design, characterization and correlation with statistical process controls. The LT8471I is guaranteed over the full $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$. The LT8471H is guaranteed over the full $-40^{\circ} \mathrm{C}$ to $150^{\circ} \mathrm{C}$ operating junction temperature range. Operating lifetime is derated at junction temperatures greater than $125^{\circ} \mathrm{C}$.

Note 3: Current limit guaranteed by design and/or correlation to static test.
Note 4: Current Limit measured at equivalent switching frequency of 1 MHz .
Note 5: This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed $150^{\circ} \mathrm{C}$ when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.
Note 6: Low side and high side configurations are discussed in the Switch Configurations and the Skyhook Regulator section.
Note 7: Minimum switch on-time, off-time is guaranteed by design.

TYPICAL PGRFORMAOCE CHARACTERISTICS $T_{A}=25^{\circ} \mathrm{C}$, unless otherwise specified.

TYPICAL PGRFORMANCE CHARACTERISTICS $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise specified.

## PIn functions

C1, C2 (Pins 1, 20): Collector Pins. These are the collectors of the primary internal NPN power switches. If either pin is tied to a DC voltage, it must be locally bypassed; if either pin is a switching pin, minimize trace area connected to the pin to minimize EMI. When the Skyhook channel is used, the C2 pin must be tied to the input voltage of the Skyhook channel.

C3 (Pin 13): Skyhook Collector Pin. This is the collector of the internal NPN power switch for the Skyhook channel. If the Skyhook channel is used, minimize the metal trace area connected to this pin to minimize EMI. If the Skyhook channel is not used, tie the C3 pin to GND.

E1, E2 (Pins 2, 19): Emitter Pins. These are the emitters of the primary internal NPN power switches. Unless grounded, minimize trace area connected to these pins to minimize EMI.

FB1, FB2 (Pins 5, 16): Feedback Pins for Primary Channels. Connect a resistor divider between $\mathrm{V}_{0 \mathrm{UT}}$, FB and GND to set the output voltage.
GND (Pins 10, 11,12, Exposed Pad 21): Ground. All of the ground pins must be soldered directly to the local ground plane. The exposed pad metal of the package provides both electrical contact to ground and good thermal contact to the printed circuit board.
OV/UV (Pin 6): Overvoltage/UndervoltagePin. Tieto 1.215V (typical) ormore to enable the device; ground to shut down. Configurable as a UVLO and OVLO by connecting to an external resistor divider. See the Applications Information section for more information.

PG1, PG2 (Pins 4, 17): Power Good Pins. Connect pull-up resistors to these pins. These open-drain output pins are
pulled low when their respective output voltages are more than $7.5 \%$ below their target output voltages (as set by the external feedback resistors). When the output voltage is above $92.5 \%$ of the target voltage, the respective PG pin driver turns off, allowing the PG voltage to rise and indicate that the regulated output voltage is good.
RT (Pin 7): Timing Resistor Pin. Adjusts the switching frequency. Place a resistor from this pin to ground to set the frequency to a fixed free-running level. Do not float this pin.
SHOUT (Pin 14): Skyhook Output Voltage Pin. This is the cathode of the internal Schottky diode and the output of the Skyhook boost converter.

SS1, SS2 (Pins 8, 15): Soft Start Pins. Place a soft-start capacitor on each pin. Upon start-up, the SS pins will be charged by (nominally) 250k resistors to about 2.15V.

SYNC (Pin 9): To synchronize the switching frequency to an outside clock, simply drive this pin with a clock. The high voltage level of the clock needs to exceed 1.3 V , and the low level should be less than 0.4 V . Drive this pin to less than 0.4 V to revert to the internal free running clock. See the Applications Information section for more information.
$\mathbf{V}_{\text {IN1 }}$ (Pin 3): Input Supply Pin 1. This is the power supply pin for primary channel 1 and the Skyhook channel. This pin also provides power to additional circuitry common to all channels. $\mathrm{V}_{\mathrm{IN} 1}$ must be greater than 2.6 V for any channel to operate. $\mathrm{V}_{\mathrm{IN} 1}$ must be locally bypassed.
$\mathbf{V}_{\text {IN2 }}$ (Pin 18): Input Supply Pin 2. This is the power supply pin for primary channel 2 and must be greater than 2.6 V when channel 2 is in use. $\mathrm{V}_{\text {IN2 }}$ must be locally bypassed.

## LT8471

BLOCK DIAGRAM

## operation

The LT8471 consists of two primary channels, each with a 2 A power switch. One Skyhook channel is also available with a 500 mA power switch to support the primary channels when performing step-down conversions. The maximum voltage between $\mathrm{V}_{\text {IN1 }}$ and E 1 (or $\mathrm{V}_{\text {IN2 }}$ and E ) is 40 V when E1 (orE2) is grounded. This is the case for boost, SEPIC, flyback and dual-inductor inverting topologies. The maximum allowed voltage between $\mathrm{V}_{\text {IN1 }}$ and E1 (or $\mathrm{V}_{\text {IN2 }}$ and E 2 ) is 60 V when E 1 (or E 2 ) is allowed to toggle, such as in buck, ZETA and single-inductor inverting topologies.

## Primary Channels

The two primary channels, 1 and 2, can be independently configured as boost, buck, SEPIC, ZETA, flyback or inverting $D C / D C$ converters to adapt into various applications. Both channels use a constant-frequency, current mode control scheme to provide line and load regulation (refer to the Block Diagram). The channel 1 clock is in phase with the internal oscillator or the SYNC pin if it is toggling. In order to reduce transient switching spikes, the clock for channel 2 is approximately $180^{\circ}$ out-of-phase with the channel 1 clock.

At the start of each clock phase, an SR latch (SR11/SR12 in the Block Diagram) is set, turning on the internal power switch (Q1/Q2 in the Block Diagram) for the respective channel. An amplifier (A41/A42 in the Block Diagram) and a comparator (A31/A32 in the Block Diagram) monitor the current flowing through the internal power switch, turning the switch off when the current reaches a level determined by the voltage at VC1/VC2. An error amplifier measures the output voltage through an external resistor divider tied to the FB1/FB2 pin and servos the VC1/VC2 voltage. If the error amplifier's output (VC1/VC2) increases, more current is delivered to the output; if it decreases, less current is delivered. An internal clamp on the VC1/VC2 voltage provides current limit.
Both of the primary channels contain a power good comparator which trips when the corresponding FB pin voltage is at $92.5 \%$ of its regulated value. The PG1 and PG2 outputs are driven by open-drain N -channel MOSFET devices that are off when the respective output is in regulation, allowing external resistors to pull the PG1/PG2 pins high. The

PG1 and PG2 pin states are only valid when the respective channel is enabled and $\mathrm{V}_{\mathrm{IN} 1}$ is above 2.6 V .

## Skyhook Channel

When either channel is configured as a buck, ZETA or single-inductor inverting converter, the respective $\mathrm{V}_{\text {IN }}$ pin(s) must be boosted above the input voltage, $\mathrm{V}_{\mathrm{CC}}$. The boosted supply provides base current to the appropriate Q1 and/or Q2 NPN power switch. The Skyhook channel provides this boosted voltage to the SHOUT pin which must also be connected to $\mathrm{V}_{\text {IN2 }}$ and/or $\mathrm{V}_{\text {IN1 }}$ as needed.
The Skyhook is a constant-frequency, voltage mode boost converter including a Schottky diode integrated on chip. The Skyhook output, SHOUT, is regulated to a fixed voltage (4.25V typical) above the C 2 pin which must be connected to a DC voltage (typically $\mathrm{V}_{\text {CC }}$ ). If the Skyhook is not needed it can be disabled by tying the C3 pin to GND. This also reduces the current draw from $\mathrm{V}_{\text {IN1 }}$. Refer to the Applications Information section for more information about the proper use of the Skyhook channel.
The Skyhook operates as follows: An error amplifier measures the output voltage (SHOUT) through the SHOUT-C2 voltage comparator and servos an internal control voltage. The control voltage determines the on-time of the Q3 power switch for each cycle, and thus, the amount of current being delivered to SHOUT. Loop compensation is integrated in the chip. Comparator A43 monitors the current in the power switch Q3 in order to detect over current conditions. If current in excess of 500 mA (typ) is detected, switch Q3 is immediately turned off.

## Start-Up Operation

Several functions are provided to enable a clean start-up for the LT8471.

- First, the OV/UV pin voltage is monitored by an internal voltage reference to give a precise turn-on voltage range. An external resistor (or resistor divider) can be connected from the input power supply to the OV/UV pin to provide a user-programmable undervoltage and overvoltage lockout function.
- Second, the soft-start circuitry provides for a gradual ramp-up of the switch current for the primary channels

## operation

and a gradual ramp-up of duty cycle for the Skyhook channel. When the part is brought out of shutdown, the external SS capacitors are first discharged (providing protection against OV/UV pin glitches and slow ramping). Next, internal 250k resistors pull the SS pins up to $\sim 2.15 \mathrm{~V}$. By connecting an external capacitor to each of the SS pins, the voltage ramp rates on the pins can be set. Typical values for the soft-start capacitor range from 100 nF to $1 \mu \mathrm{~F}$.

- Finally, the primary channels' switching frequency is folded back by 2,4 , or 8 times when the corresponding FB pin voltage is below certain thresholds (see the Typical Performance Characteristics section). This feature reduces the minimum duty cycle that the part
can achieve, thus allowing better control of the switch current during start-up. The slope compensation function is disabled during foldback to increase the available current that can be delivered to the output.

## Thermal Shutdown Operation

Not shown in the Block Diagram is the thermal shutdown circuit. Ifthe temperature ofthe partexceeds approximately $164^{\circ} \mathrm{C}$, the SR21 and SR22 latches are set. A full soft-start cycle will then be initiated after the temperature drops below approximately $162.5^{\circ} \mathrm{C}$. The thermal shutdown circuit protects the power switches as well as the external components connected to the LT8471.

## APPLICATIONS INFORMATION

## Input Supply Requirements

$\mathrm{V}_{\text {IN1 }}$ is the main power supply of the LT8471. It powers channel 1, the Skyhook channel and most of the internal control and bias circuits for both channels. It must be powered up to enable any channel of the LT8471. VIN2 is the power supply for channel 2 , and only needs to be powered up when channel 2 is used. When $\mathrm{V}_{\text {IN2 }}$ is not powered up, channel 2 will shut down.

## Switch Configurations and the Skyhook Regulator

The primary channel NPN power switches can be connected in low side or high side configurations. A low side connection is when the power switch is on the lower voltage side of the inductor while the switch is on. The boost, SEPIC, flyback and dual-inductor inverting configurations use low side power switches. Conversely, a high side connection is when the power switch is on the higher voltage side of the inductor when it is on. The buck, ZETA and single-inductor inverting configurations use high side power switches. Channels 1 and 2 can be configured for high side or low side switching and do not need to be configured in the same way as the other.

In the low side configurations, the E pin is typically tied to ground and the respective C pin toggles. VIN for the respective channel must operate in a range of 2.6 V to 40 V .
High side configurations require that the $C$ pin be tied to a positive DCvoltage supply and the respective Epin toggles. The channel's $\mathrm{V}_{\text {IN }}$ pin should be at least 2.2 V (typical) higher than the respective C pin to provide adequate drive to the base of the NPN power switch. When configured with a high side switch, the channel's $V_{\text {IN }}$ can operate up to 50 V above ground, 60 V above the respective E pin voltage, and 40 V above the respective C pin voltage.

The Skyhook boost regulator is available to provide additional $V_{I N}$ Voltage when it is needed to support high side switch topologies. When enabled, the Skyhook output voltage (SHOUT) is regulated to 4.25 V (typical) above the C 2 pin voltage. Figure 1 shows an example where the application input voltage is 6 V to 32 V . The Skyhook boost converter regulates SHOUT, $\mathrm{V}_{\text {IN1 }}$ and $\mathrm{V}_{\text {IN2 }}$ to 10.25 V to 36.25 V insuring that the $\mathrm{V}_{\text {IN1 }}$ and $\mathrm{V}_{\text {IN2 }}$ pins are typically 4.25 V above the C 1 and C 2 pins. More information about the Skyhook regulator is available in later sections.

## APPLICATIONS Information

## Internal Undervoltage Lockouts

The LT8471 monitors $\mathrm{V}_{\text {IN } 1}$ and $\mathrm{V}_{\text {IN } 2}$ supply voltages in case either drops below a minimum operating level (typically about 2.35 V and 2.25 V , respectively).

When $\mathrm{V}_{\text {IN1 }}$ is detected low, all power switches are deactivated, and while sufficient $\mathrm{V}_{\text {IN1 }}$ voltage persists, the soft-start capacitors for both SS1 and SS2 are discharged. After $\mathrm{V}_{\text {IN } 1}$ is detected high, the channel 1 power switch is re-enabled and SS1 begins charging.

When $\mathrm{V}_{\text {IN2 }}$ is detected low, the channel 2 power switch is deactivated, and while sufficient $\mathrm{V}_{\mathrm{IN} 1}$ voltage persists, the soft-start capacitor for SS2 is discharged. After both VIN1 and $\mathrm{V}_{\text {IN2 }}$ are detected high, the channel 2 power switch is re-enabled and SS2 begins charging.

## Oscillator

The internal free-running oscillator can set the operating frequency of the LT8471. When the SYNC pin is driven low ( $<0.4 \mathrm{~V}$ ), the frequency of operation is set by a resistor from RT to ground. An internally trimmed timing capacitor resides inside the IC. The oscillator frequency is calculated using the following formula:

$$
f_{O S C}=\frac{85.5}{R_{T}+1}
$$

where $f_{\text {OSC }}$ is in $M H z$ and $R_{T}$ is in $k \Omega$. Conversely, $R_{T}$ (in $k \Omega$ ) can be calculated from the desired frequency (in MHz ) using:

$$
R_{T}=\frac{85.5}{f_{\text {OSC }}}-1
$$

## Clock Synchronization

The operating frequency of the LT8471 can be synchronized to an external clock source. To synchronize to the external source, simply provide a digital clock signal into the SYNC pin. The LT8471 will operate at the SYNC clock frequency. The LT8471 will revert to the internal freerunning oscillator clock after SYNC is driven low for a few free-running clock cycles.

Driving SYNC high for an extended period of time effectively stops the operating clock and prevents latches SR11 and SR12 from becoming set (see the Block Diagram). As a result, the switching operation of the LT8471 stops, and all the power switches are turned off.
The duty cycle of the SYNC signal must be between $35 \%$ and $65 \%$ for proper operation. Also, the frequency of the SYNC signal must meet the following two criteria:

1. SYNC may not toggle outside the frequency range of 100 kHz to 2 MHz unless it is set low to enable the freerunning oscillator.
2. The SYNC frequency can always be higher than the free-running oscillator frequency, fosc, but should not be less than $25 \%$ below fosc.

## Operating Frequency Selection

There are several considerations in selecting the operating frequency of the converter. The first is staying clear of sensitive frequency bands, which cannot tolerate any spectral noise. For example, in products incorporating RF communications, the 455 kHz IF frequency is sensitive to any noise, therefore switching above 600 kHz is desired. Some communications have sensitivity to 1.1 MHz , and in that case, a 1.5 MHz switching converter frequency may be employed. The second consideration is the physical size of the converter. As the operating frequency goes up, the inductor and filter capacitors go down in value and size. The trade-off is efficiency, since the switching losses due to NPN base charge (see the Power and Thermal Calculation section), Schottky diode charge, and other capacitive loss terms increase proportionally with frequency.

## Soft-Start

The LT8471 contains soft-start circuitry to limit peak switch currents during start-up. High start-up current is inherent in switching regulators since the feedback loop is saturated due to $\mathrm{V}_{\text {OUT }}$ being far from its final value. The regulator tries to charge the output capacitor as quickly as possible, which results in large peak currents.
The start-up current can be limited by connecting external capacitors (typically 100 nF to $1 \mu \mathrm{~F}$ ) to the SS1 and SS2 pins. The capacitors are slowly charged to $\sim 2.15 \mathrm{~V}$ by internal

## APPLICATIONS INFORMATION

250 k resistors after the part is activated. SS1 pin voltages below $\sim 0.8 \mathrm{~V}$ reduce the duty cycle of the Skyhook channel, and below $\sim 1.4 \mathrm{~V}$ reduce the current limit of channel 1 . SS2 voltages below $\sim 1.4 \mathrm{~V}$ reduce the current limit of channel 2. Thus, the gradual ramping of the SS voltages also gradually increases the current limits of the primary channels and the duty cycle of the Skyhook channel. This, in turn, allows the output capacitors for each channel to charge gradually toward its final value while limiting the start-up currents.

Inthe event of a shutdown (OV/UV pin), internal undervoltage lockout (UVLO) or a thermal lockout, the soft-start capacitors are automatically discharged to $<50 \mathrm{mV}$ before charging resumes, assuring that the soft-starting occurs after every reactivation of the chip.

## Shutdown

The OV/UV pin is used to enable and disable the chip. When configured properly, the OV/UV pin can serve as both an undervoltage and an overvoltage detector as discussed further in the next section. When the OV/UV voltage is below 1.215 V (typ) switching activity is disabled as shown in Figure 1 (lockout state). When OV/UV is below 300 mV ,

Figure 1. Chip States vs OV/UV Voltage
quiescent current becomes very low and the part is completely in shutdown. Voltages between 1.215 V and 1.37 V enable the part (ACTIVE state) for normal operation. The OV/UV pin is internally clamped to approximately 1.37 V and should always be connected through a resistor to limit the current. If the OV/UV pin current exceeds $80 \mu \mathrm{~A}$ (typ), switching is disabled and the part enters the lockout state. See the OV/UV pin current graph in the Typical Performance Characteristics section.

When in the lockout state, the power switches are disabled and the SR21 and SR22 latches are set. This causes the soft-start capacitors to discharge until active operation is enabled. Although the power switches are disabled, the lockout state does not necessarily reduce quiescent current until the OV/UV voltage is near or below the shutdown threshold.

Due to the 1.37 V clamping circuit, OV/UV should always be connected through a resistor to limit the current. If the over and undervoltage functions are not used, the OV/UV pin can be driven digitally through a current limiting resistor.

Figure 2 shows how to configure an overvoltage lockout (OVLO) and/or undervoltage lockout (UVLO) for the

Figure 2. Configurable OVLO and UVLO

## APPLICATIONS INFORMATION

LT8471. Comparator CUVLO detects undervoltage conditions by comparing the OV/UV pin to typical thresholds of 1.215 V (rising) and 1.18 V (falling). The COVLO comparator detects over voltage conditions by comparing the OV/UV pin current to typical thresholds of $80 \mu \mathrm{~A}$ (rising) and $75 \mu \mathrm{~A}$ (falling).
Possible reasons to use the UVLO and/or OVLO functions are as follows: A switching regulator draws constant power from the source, so source current increases as source voltage drops. This looks like a negative resistance load to the source and can cause the source to current-limit or latch up under low source voltage conditions. UVLO prevents the regulator from operating at source voltages where these problems might occur. The OVLO function is used to stop the switching regulator(s) in cases where the input supply voltage overshoots higher than desired.
As an example, $\mathrm{V}_{\mathrm{IN} 1}$ overvoltage and undervoltage thresholds can be set independently by properly choosing $R_{3 A}$ and $R_{3 B}$. Use the following formulas to determine the resistor values:

$$
\left.\begin{array}{l}
\mathrm{R}_{3 \mathrm{~A}}=\left(\frac{\mathrm{V}_{\mathrm{OVLO}}+}{80 \mu \mathrm{~A}}\right)-\left(\frac{1.37 \cdot \mathrm{~V}_{\mathrm{UVLO}}}{}\right) \\
\mathrm{R}_{3 \mathrm{~B}}=\left(\frac{1.18 \cdot 80 \mu \mathrm{~A}}{\mathrm{~V}_{\mathrm{UVLO}}}-1.18\right.
\end{array}\right) \cdot \mathrm{R}_{3 \mathrm{~A}}
$$

where:
$\mathrm{V}_{\text {OVLO }}+$ is the desired rising OVLO threshold
$\mathrm{V}_{\mathrm{UVLO}}-$ is the desired falling UVLO threshold

After $R_{3 A}$ and $R_{3 B}$ have been selected, the UVLO and OVLO rising and falling thresholds can be determined using:

$$
\begin{aligned}
& V_{0 V L 0^{+}}=1.37 \cdot\left(\frac{R_{3 A}+R_{3 B}}{R_{3 B}}\right)+80 \mu A \cdot R_{3 A} \\
& V_{0 V L O^{-}}=1.37 \cdot\left(\frac{R_{3 A}+R_{3 B}}{R_{3 B}}\right)+75 \mu A \cdot R_{3 A} \\
& V_{U V L 0^{+}}=1.215 \cdot\left(\frac{R_{3 A}+R_{3 B}}{R_{3 B}}\right) \\
& V_{U V L 0^{-}}=1.18 \cdot\left(\frac{R_{3 A}+R_{3 B}}{R_{3 B}}\right)
\end{aligned}
$$

where:
$\mathrm{V}_{\text {OVLO }}+$ and $\mathrm{V}_{\text {OVLO- }}$ are the rising and falling OVLO thresholds, respectively.
VuvLO+ and VuvLO- $^{-}$are the rising and falling UVLO thresholds, respectively.
There are a few limitations in selecting the OVLO and UVLO threshold voltages.

1. The UVLO threshold must be at least 2.6 V so that it's higher than the minimum operating voltage the input supply. If the UVLO function is not needed, $\mathrm{R}_{3 B}$ can be omitted and $\mathrm{R}_{3 \mathrm{~A}}$ can be calculated using:

$$
R_{3 A}=\left(\frac{\mathrm{V}_{\mathrm{oVLO}^{+}}-1.37 \mathrm{~V}}{80 \mu \mathrm{~A}}\right)
$$

2. The following relationship must be satisfied:

$$
\frac{\mathrm{V}_{\mathrm{OVLO}^{+}}}{\mathrm{V}_{\mathrm{UVLO}}}{ }^{-}-\frac{1.37}{1.18}=1.161
$$

As the ratio of $\mathrm{V}_{\text {OVLO }}$ to $\mathrm{V}_{\text {UVLO }}$ gets closer to 1.161, the required resistances for $R_{3 A}$ and $R_{3 B}$ become smaller, thus increasing the operating current.

## APPLICATIONS INFORMATION

The following example shows how to select $R_{3 A}$ and $R_{3 B}$ to disable the LT8471 for $\mathrm{V}_{\mathrm{IN} 1}$ voltages below 5 V and above 15 V .

First, check that the ratio of the OVLO to the UVLO threshold is greater than 1.161 . Here, the ratio is $15 \mathrm{~V} / 5 \mathrm{~V}=3 \mathrm{~V}$, which satisfies the second rule just mentioned.
Next, calculate:

$$
\mathrm{R}_{3 \mathrm{~A}}=\frac{15 \mathrm{~V}}{80 \mu \mathrm{~A}}-\frac{1.37 \cdot 5 \mathrm{~V}}{1.18 \cdot 80 \mu \mathrm{~A}}=114.9 \mathrm{k}
$$

Choose $R_{3 A}$ to be a standard value resistance of 118 k . Next, calculate:

$$
R_{3 B}=\left(\frac{1.18 \mathrm{~V}}{5 \mathrm{~V}-1.18 \mathrm{~V}}\right) \cdot 118 \mathrm{k}=36.5 \mathrm{k}
$$

Choose $R_{3 B}$ to be a standard value resistance of 36.5 k .
After selecting the standard value resistors for $R_{3 A}$ and $\mathrm{R}_{3 B}$, calculate the final thresholds using the formulas previously provided.

$$
\begin{aligned}
\mathrm{V}_{\mathrm{OVLO}^{+}} & =1.37 \cdot\left(\frac{118 \mathrm{k}+36.5 \mathrm{k}}{36.5 \mathrm{k}}\right)+80 \mu \mathrm{~A} \cdot 118 \mathrm{k} \\
& =15.24 \mathrm{~V} \\
\mathrm{~V}_{\mathrm{OVLO}^{-}} & =1.37 \cdot\left(\frac{118 \mathrm{k}+36.5 \mathrm{k}}{36.5 \mathrm{k}}\right)+75 \mu \mathrm{~A} \cdot 118 \mathrm{k} \\
& =14.65 \mathrm{~V} \\
\mathrm{~V}_{\mathrm{UVLO}^{+}} & =1.215 \cdot\left(\frac{118 \mathrm{k}+36.5 \mathrm{k}}{36.5 \mathrm{k}}\right)=5.14 \mathrm{~V} \\
\mathrm{~V}_{\mathrm{UVLO}^{-}} & =1.18 \cdot\left(\frac{118 \mathrm{k}+36.5 \mathrm{k}}{36.5 \mathrm{k}}\right)=4.99 \mathrm{~V}
\end{aligned}
$$

## Setting the Output Voltage (Primary Channels)

The output voltage is programmed with a resistor divider between the output and the FB pin. Choose 1\% or better resistors according to:

$$
R_{A}=R_{B} \cdot\left(\frac{V_{O U T}}{V_{F B}}-1\right)
$$

where $\mathrm{V}_{\text {FB }}$ is the feedback voltage ( 0.789 V typical for positive $\mathrm{V}_{\text {OUT }}$ and -0.788 V for negative $\mathrm{V}_{\text {OUT }}$ ). Reference designators are as shown in the Block Diagram.
For example, for $V_{O U T}=10 \mathrm{~V}$, choose $R_{1 B}=10 k$, then choose:

$$
R_{1 \mathrm{~A}}=10 \mathrm{k} \cdot\left(\frac{10 \mathrm{~V}}{0.789 \mathrm{~V}}-1\right) \simeq 115 \mathrm{k}
$$

## Start-Up Sequencing

Connecting one primary channel's PG pin to the other channel's SS pin is an easy way to sequence the start-up order of the outputs. For example, in most applications, connecting PG1 to SS2 will make the channel 1 output come up before the channel 2 output during the start-up. Because the skyhook channel does soft-start with the SS1 pin (see more details in the Soft-Start section), the following guidelines need to be applied if both power-up sequencing and the skyhook channel are used:

1. Connect PG1 directly to SS2 to make channel 1 's output come up first (see Figure 12).
2. Connect a 147 k resistor between PG2 and SS1 to make channel 2's output come up first.
An example using a 147 k resistor connected between PG2 and SS1 is shown in Figure 9a. In this application, channel 1 is configured as a boost converter, and channel 2 is configured as a buck converter. The buck converter has to start up first as its output is connected to the input of the boost converter.

## APPLICATIONS INFORMATION

## Power Switch Duty Cycle (Primary Channels)

In order to maintain loop stability and deliver adequate current to the load, the internal power switches (Q1 and Q2 in the Block Diagram) cannot remain on for $100 \%$ of each clock cycle. The maximum allowable duty cycle is given by:

$$
\mathrm{DC}_{\text {MAX }}=\left(\frac{\mathrm{T}_{\mathrm{P}}-\mathrm{MIN}_{(\text {OFFF)TIME }}}{T_{\mathrm{P}}}\right) \cdot 100 \%
$$

where $T_{p}$ is the clock period and $\mathrm{MIN}_{\text {(OFF)TIME }}$ is typically 170ns (refer to the Electrical Characteristics section).
The application should be designed so that the steady state duty cycle does not exceed $D C_{\text {max }}$. Duty cycle equations for several common topologies are given below, where $V_{D}$ is the diode forward voltage drop and $\mathrm{V}_{\text {CESAT }}$ is typically 300 mV at 1.5 A .

$$
\begin{aligned}
& D C_{\text {BOOST }} \cong \frac{V_{\text {OUT }}-V_{C C}+V_{D}}{V_{\text {OUT }}+V_{D}-V_{\text {CESAT }}} \\
& D C_{\text {BUCK }} \cong \frac{V_{\text {OUT }}+V_{D}}{V_{\text {CC }}+V_{D}-V_{\text {CESAT }}} \\
& D C_{1 L \_I N V} \cong \frac{\left|V_{\text {OUT }}\right|+V_{D}}{V_{\text {CC }}+V_{D}-V_{\text {CESAT }}+\left|V_{\text {OUT }}\right|} \\
& D C_{2 L \_I N V} \cong \frac{\left|V_{\text {OUT }}\right|+V_{D}}{V_{\text {CC }}+V_{D}-V_{\text {CESAT }}+\left|V_{\text {OUT }}\right|} \\
& D C_{\text {SEPIC }} \cong \frac{V_{D}+V_{\text {OUT }}}{V_{\text {CC }}+V_{\text {OUT }}+V_{D}-V_{\text {CESAT }}} \\
& D C_{\text {ZETA }} \cong \frac{V_{D}+V_{\text {OUT }}}{V_{\text {CC }}+V_{\text {OUT }}+V_{D}-V_{\text {CESAT }}}
\end{aligned}
$$

where $\mathrm{V}_{\mathrm{CC}}$ is the positive input voltage to the $\mathrm{DC} / \mathrm{DC}$ converter. See the Typical Applications section for examples.
The LT8471 can be used in configurations where the duty cycle is higher than $\mathrm{DC}_{\mathrm{MAX}}$, but it must be operated in the discontinuous conduction mode so that the effective duty cycle is reduced.

## Inductor Selection (Primary Channels)

General Guidelines: The high frequency operation of the LT8471 allows for the use of small surface mount inductors. For high efficiency, choose inductors with high frequency core material, such as ferrite, to reduce core losses. To improve efficiency, choose inductors with more volume for a given inductance. The inductor should have low DCR (copper wire resistance) to reduce $I^{2} \mathrm{R}$ losses, and must be able to handle the peak inductor current without saturating. Note that in some applications, the current handling requirements of the inductor can be lower, such as in the SEPIC topology, where each inductor only carries a fraction of the total switch current. Molded chokes or chip inductors usually do not have enough core area to support peak inductor currents in the 2 A to 3 A range. To minimize radiated noise, use a toroidal or shielded inductor. Note that the inductance of shielded core types will drop more as current increases, and will saturate more easily. See Table 1 for a list of inductor manufacturers. Thorough lab evaluation is recommended to verify that the following guidelines properly suit the final application.
Table 1. Inductor Manufacturers

| VENDOR | PART NUMBER | WEB |

| Coilcraft | MSS1038, MSS7341 and <br> LPS4018 | www.coilcraft.com |
| Coiltronics | DR, LD and CD Series | www.coiltronics.com |
| Sumida | CDRH105R Series | www.sumida.com |
| Würth Elektronik | WE-LHMI and WE-TPC Series | www.we-online.com |

Minimum Inductance: Although there can be a tradeoff with efficiency, it is often desirable to minimize board space by choosing smaller inductors. When choosing an inductor, there are two conditions that limit the minimum inductance; (1) providing adequate load current, and (2) avoiding subharmonic oscillation. Choose an inductance that is high enough to meet both of these requirements.

## APPLICATIONS INFORMATION

Adequate Load Current: Small value inductors result in increased ripple currents and thus, due to the limited peak switch current, decrease the average current that can be provided to a load (lout). In order to provide adequate load current, L should be at least:

$$
\begin{aligned}
& L_{\text {BOOST }}>\frac{D C \cdot V_{C C}}{2 \bullet f \bullet\left(I_{\text {LIM }}-\frac{V_{O U T} \bullet I_{O U T}}{V_{C C} \bullet \eta}\right)} \\
& L_{\text {BUCK }}>\frac{D C \cdot\left(V_{C C}-V_{O U T}\right)}{2 \bullet f \cdot\left(I_{\text {LIM }}-\frac{V_{O U T} \cdot I_{O U T}}{V_{C C} \bullet \eta}\right)} \\
& L_{\text {SEPIC }}>\frac{D C \bullet V_{C C}}{2 \bullet f \bullet\left(I_{\text {LIM }}-\frac{V_{\text {OUT }} \bullet I_{O U T}}{V_{C C} \bullet \eta}-I_{O U T}\right)} \\
& L_{1 L} \text { INV }>\frac{D C \cdot V_{\text {CC }}}{2 \cdot f \cdot\left(I_{\text {LIM }}-\frac{\left|V_{\text {OUT }}\right| \cdot I_{O U T}}{V_{C C} \cdot \eta}\right)} \\
& L_{2 L \_I N V}>\frac{D C \cdot V_{C C}}{2 \cdot f \cdot\left(I_{\text {LIM }}-\frac{\left|V_{O U T}\right| \cdot I_{O U T}}{V_{C C} \cdot \eta}-I_{O U T}\right)} \\
& L_{\text {ZETA }}>\frac{D C \bullet V_{C C}}{2 \bullet f \bullet\left(I_{\text {LIM }}-\frac{\left|V_{O U T}\right| \bullet I_{O U T}}{V_{C C} \bullet \eta}-I_{O U T}\right)}
\end{aligned}
$$

where:
$\mathrm{L}=\mathrm{L} 1| | \mathrm{L} 2$ for dual uncoupled inductor topologies.
$\mathrm{L}=\mathrm{L} 1=\mathrm{L} 2$ for dual-coupled inductor topologies.
DC = Switch duty cycle in steady state.
$\mathrm{l}_{\text {LIM }}=$ Switch current limit, typically about 2.3A at 50\% duty cycle (see the Typical Performance Characteristics section).
$\eta=$ Power conversion efficiency (typically 88\% for boost, $75 \%$ for dual inductor, $85 \%$ for buck and $80 \%$ for 1 L inverting topologies at high currents).
$V_{C C}=$ Positive input voltage to the DC/DC converter. See the Typical Applications section for examples.
$f=$ Switching frequency.
Negative values of $L$ indicate that the output load current Iout exceeds the switch current limit capability of the LT8471.
Avoiding Subharmonic Oscillations: The LT8471's internal slope compensation circuit will prevent subharmonic oscillations that can occur when the duty cycle is greater than $50 \%$, provided that the inductance exceeds a minimum value. In applications that operate with duty cycles greater than $50 \%$, the inductance must be at least:

$$
\begin{aligned}
& L_{\text {BOOST }}>\frac{V_{C C} \bullet(2 \cdot D C-1)}{(1-D C) \cdot f} \\
& L_{S E P I C}>\frac{V_{C C} \cdot(2 \cdot D C-1)}{(1-D C) \cdot f} \\
& L_{2 L} \text { INV }>\frac{V_{C C} \cdot(2 \cdot D C-1)}{(1-D C) \cdot f} \\
& L_{\text {BUCK }}>\frac{V_{C C} \cdot(2 \cdot D C-1)}{f} \\
& \mathrm{~L}_{1 L_{-} \mathrm{INV}}>\frac{\mathrm{V}_{C C} \cdot(2 \cdot \mathrm{DC}-1)}{(1-\mathrm{DC}) \cdot f} \\
& L_{\text {ZETA }}>\frac{V_{C C} \bullet(2 \cdot D C-1)}{(1-D C) \cdot f}
\end{aligned}
$$

where:
$\mathrm{L}=\mathrm{L} 1 \| \mathrm{L} 2$ for dual uncoupled inductor topologies.
$L=L 1=L 2$ for dual-coupled inductor topologies.
DC = Switch duty cycle in steady state.
$V_{C C}=$ Positive input voltage to the DC/DC converter. See the Typical Applications section for examples.
$f=$ Switching frequency.

## APPLICATIONS INFORMATION

Maximum Inductance: Excessive inductance can reduce current ripple to levels that are difficult for the current comparator (A3 in the Block Diagram) to easily distinguish, thus causing duty cycle jitter and/or poor regulation. The maximum inductance can be calculated using:

$$
\mathrm{L}_{\mathrm{MAX}}=\frac{\mathrm{V}_{\text {CC }}-\mathrm{V}_{\text {CESAT }}}{\mathrm{I}_{\mathrm{MIN(RIPPLE})} \bullet f} \bullet \mathrm{DC}
$$

for inverting, boost, ZETA and SEPIC topologies, or:

$$
L_{\text {MAX }}=\frac{(1-D C) \bullet V_{\text {CC }}-V_{\text {CESAT }}}{I_{\text {MIN(RIPPLE }} \cdot \mathrm{f}} \cdot \mathrm{DC}
$$

for the buck topology.
where:
$L_{\text {MAX }}=L 1| | L 2$ for dual uncoupled inductor topologies.
$L_{\text {MAX }}=L 1=L 2$ for dual-coupled inductor topologies.
$I_{\text {(MIN)RIPPLE }}$ is typically 120 mA .
$D C=$ Switch duty cycle in steady state.
$V_{C C}=$ Positive input voltage to the DC/DC converter. See the Typical Applications section for examples.
$f=$ Switching frequency.

Maximum Current Rating: Finally, the inductor(s) must be rated to handle the peak operating current to prevent inductor saturation resulting in efficiency loss. In steady state, the peak input inductor current (continuous conduction mode only) is given by:

$$
\begin{aligned}
& L_{\text {_PEAK }}=\frac{\left|V_{O U T} \bullet I_{\text {OUT }}\right|}{V_{C C} \bullet \eta}+\frac{\left(V_{C C}-V_{\text {CESAT }}\right) \bullet D C}{2 \bullet L \bullet f}(B O O S T) \\
& L_{L_{-} \text {PEAK }}=\frac{\left|V_{\text {OUT }} \cdot I_{\text {OUT }}\right|}{V_{C C} \cdot \eta}+\frac{\left(V_{C C}-V_{\text {CESAT }}\right) \cdot D C}{2 \cdot L \bullet f}\left(1 L_{-} I N V\right) \\
& I_{L_{-} P E A K}=I_{O U T}+\frac{\left(V_{C C}-V_{C E S A T}\right) \cdot D C \cdot(1-D C)}{2 \bullet L \bullet f}(B U C K) \\
& L_{\text {L1_PEAK }}=\frac{\left|V_{\text {OUT }} \bullet I_{O U T}\right|}{V_{C C} \bullet \eta}+\frac{\left(V_{\text {CC }}-V_{\text {CESAT }}\right) \cdot D C}{2 \bullet L 1 \bullet f}(\text { SEPIC }) \\
& L_{\text {L2_PEAK }}=I_{O U T}+\frac{\left(V_{O U T}+V_{D}\right) \cdot(1-D C)}{2 \cdot L 2 \cdot f}(\text { SEPIC }) \\
& L_{\text {L1_PEAK }}=\frac{\left|V_{O U T} \bullet I_{\text {OUT }}\right|}{V_{C C} \bullet \eta}+\frac{\left(V_{C C}-V_{C E S A T}\right) \cdot D C}{2 \cdot L 1 \bullet f}\left(2 L_{-} \text {INV }\right) \\
& L_{\text {L2_PEAK }}=I_{O U T}+\frac{\left(\left|V_{O U T}\right|+V_{D}\right) \cdot(1-D C)}{2 \cdot L 2 \cdot f}\left(2 L_{-} \text {INV }\right) \\
& L_{\text {L1_PEAK }}=\frac{\left|V_{O U T} \bullet I_{\text {OUT }}\right|}{V_{C C} \bullet \eta}+\frac{\left(V_{C C}-V_{\text {CESAT }}\right) \cdot D C}{2 \bullet L 1 \bullet f}(\text { ZETA }) \\
& L_{\text {L2_PEAK }}=I_{O U T}+\frac{\left(\left|V_{O U T}\right|-V_{D}\right) \cdot(1-D C)}{2 \cdot L_{2} \cdot f}(Z E T A)
\end{aligned}
$$

Note that the inductor current can be higher during load transients. It can also be higher during start-up if inadequate soft-start capacitance is used.

## APPLICATIONS INFORMATION

## Capacitor Selection (Primary Channels)

Low ESR (equivalent series resistance) capacitors should be used at the output to minimize the output ripple voltage. Multilayer ceramic capacitors are an excellent choice, as they have an extremely low ESR and are available in very small packages. X5R or X7R dielectrics are preferred, as these materials retain their capacitance over wider voltage and temperature ranges. A $4.7 \mu \mathrm{~F}$ to $20 \mu \mathrm{~F}$ output capacitor is sufficient for most applications, but systems with very low output currents may need only a $1 \mu \mathrm{~F}$ or $2.2 \mu \mathrm{~F}$ output capacitor. Always use a capacitor with a sufficient voltage rating. Many capacitors rated at $2.2 \mu \mathrm{~F}$ to $20 \mu \mathrm{~F}$, particularly 0805 or 0603 case sizes, have greatly reduced capacitance at the desired output voltage. Solid tantalum or OS-CON capacitors can be used, but they will occupy more board area than ceramic ones and will have higher ESR with greater output ripple.

Low ESR capacitors should also be used as the input decoupling capacitors, which should be placed as closely as possible to the LT8471. Ceramic capacitors make a good choice for this purpose. A $2.2 \mu \mathrm{~F}$ to $4.7 \mu \mathrm{~F}$ input capacitor is sufficient for most applications.

Table 2 shows a list of several ceramic capacitor manufacturers. Consult the manufacturers for detailed information on their entire selection of ceramic capacitors.
Table 2. Ceramic Capacitor Manufacturers

## Compensation Theory (Primary Channels)

Like all other current mode switching regulators, the primary channels of LT8471 need to be compensated for stable and efficient operation. For each primary channel, two feedback loops are used -a fast current loop which does not require compensation, and a slower voltage loop which does. In order to reduce the PCB footprint, the voltage loop compensation network is integrated inside the LT8471. Therefore, only the inductor and the output capacitor are available for adjusting the loop stability.

Standard bode plot analysis can be used to analyze and adjust the voltage feedback loop.

As with any feedback loop, identifying the gain and phase contribution of the various elements in the loop is critical. Figure 3 shows the key equivalent elements of a boost/ buck/inverting converter. Because of the fast current control loop, the power stage of the IC, inductor and diode have been replaced by a combination of the equivalent transconductance amplifier $g_{m p}$ and the current controlled current source (which converts $\mathrm{I}_{\text {VIN }}$ to $\eta \bullet \mathrm{V}_{\text {IN }} \bullet I_{\text {VIN }} / \mathrm{V}_{\text {OUT }}$ for boost converters, $I_{\text {VIN }}$ to $\eta \bullet V_{\text {IN }} \bullet D C / V_{\text {OUT }}$ for buck and single inductor inverting converters). $g_{m p}$ acts as a current source where the peak input current, $\mathrm{I}_{\mathrm{VIN}}$, is proportional to the VC voltage. $\eta$ is the efficiency of the switching regulator, and is typically about $88 \%$.

Note that the maximum output currents of $g_{m p}$ and $g_{m a}$ are finite. The limits for $g_{m p}$ are in the Electrical Characteristics section (switch current limit), and $g_{m a}$ is nominally limited to about $\pm 5 \mu \mathrm{~A}$.

CC: COMPENSATION CAPACITOR
Cout: OUTPUT CAPACITOR
$C_{\text {PL: }}$ : PHASE LEAD CAPACITOR
$g_{\text {ma }}$ : TRANSCONDUCTANCE AMPLIFIER INSIDE IC
gmp: POWER STAGE TRANSCONDUCTANCE AMPLIFIER
$R_{C}$ : COMPENSATION RESISTOR
$\mathrm{R}_{\mathrm{L}}$ : OUTPUT RESISTANCE DEFINED AS $\mathrm{V}_{\text {OUT }}$ DIVIDED BY I LOAD(MAX) Ro: OUTPUT RESISTANCE OF gma
$R_{A}, R_{B}$ : FEEDBACK RESISTOR DIVIDER NETWORK
RESR: OUTPUT CAPACITOR ESR

## APPLICATIONS INFORMATION

From Figure 3, the DC gain, poles and zeros can be calculated as follows:
DC Gain:
Boost Converters:

$$
\begin{aligned}
& A_{D C}=\left(g_{m a} \cdot R_{0}\right) \cdot g_{m p} \cdot\left(\eta \cdot \frac{V_{I N}}{V_{O U T}} \cdot \frac{R_{L}}{2}\right) \\
& \bullet \frac{R_{B}}{R_{A}+R_{B}}
\end{aligned}
$$

Buck Converters:

$$
A_{D C}=\left(g_{m a} \bullet R_{0}\right) \bullet g_{m p} \bullet\left(\eta \bullet R_{L}\right) \bullet \frac{R_{B}}{R_{A}+R_{B}}
$$

Single Inductor Inverting Converters:

$$
A_{D C}=\left(g_{\mathrm{ma}} \cdot \mathrm{R}_{0}\right) \cdot g_{\mathrm{mp}} \cdot\left(\eta \cdot \frac{\mathrm{~V}_{\mathrm{IN}}}{\mathrm{~V}_{\mathrm{IN}}+2 \cdot\left|\mathrm{~V}_{\mathrm{OUT}}\right|} \cdot \mathrm{R}_{\mathrm{L}}\right)
$$

$$
\cdot \frac{R_{B}}{R_{A}+R_{B}}
$$

Output Pole:

$$
\text { Boost Converters: } \mathrm{P} 1=\frac{2}{2 \bullet \pi \bullet R_{L} \bullet \mathrm{C}_{0 U T}}
$$

$$
\text { Buck Converters: } \mathrm{P} 1=\frac{1}{2 \bullet \pi \cdot R_{L} \cdot \mathrm{C}_{0 U T}}
$$

Single Inductor Inverting Converters:

$$
\mathrm{P} 1=\frac{2 \cdot\left|\mathrm{~V}_{\mathrm{OUT}}\right|+\mathrm{V}_{\text {IN }}}{2 \bullet \pi \cdot \mathrm{R}_{\mathrm{L}} \cdot \mathrm{C}_{\text {OUT }} \cdot\left(\mathrm{V}_{\text {IN }}+\left|\mathrm{V}_{\text {OUT }}\right|\right)}
$$

Error Amp Pole: $\mathrm{P} 2=\frac{1}{2 \bullet \pi \bullet R_{0} \bullet \mathrm{C}_{\mathrm{C}}}$
Error Amp Zero: $Z 1=\frac{1}{2 \bullet \pi \cdot R_{C} \cdot C_{C}}$
ESR Zero: $Z 2=\frac{1}{2 \cdot \pi \bullet R_{E S R} \bullet C_{O U T}}$
High Frequency Pole: P3> $\frac{f_{S}}{3}$
Phase Lead Zero: $Z 4=\frac{1}{2 \bullet \pi \bullet R_{A} \cdot C_{P L}}$
Phase Lead Pole: $\mathrm{P} 4=\frac{1}{2 \bullet \pi \cdot \mathrm{C}_{P L} \cdot \frac{R_{A} \cdot R_{B}}{R_{A}+R_{B}}}$
Error Amp Filter Pole:

$$
\mathrm{P} 5=\frac{1}{2 \cdot \pi \cdot \frac{\mathrm{R}_{\mathrm{C}} \cdot \mathrm{R}_{0}}{\mathrm{R}_{\mathrm{C}}+\mathrm{R}_{0}} \cdot \mathrm{C}_{\mathrm{F}}}, \mathrm{C}_{\mathrm{F}}<\frac{\mathrm{C}_{\mathrm{C}}}{10}
$$

RHP Zero:
Boost Converters: $Z 3=\frac{(1-D C)^{2} \cdot R_{L}}{2 \cdot \pi \cdot L}$
Buck Converters: Z3 $=\infty$
Single Inductor Inverting Converters:

$$
\mathrm{Z} 3=\frac{(1-\mathrm{DC})^{2} \cdot \mathrm{R}_{\mathrm{L}}}{2 \cdot \pi \cdot \mathrm{DC} \cdot \mathrm{~L}}
$$

## APPLICATIONS INFORMATION

Using the primary channel 1 in Figure 11a as an example, Table 3 shows the parameters used to generate the bode plot shown in Figure 4.

Figure 4. Bode Plot for Example Buck Converter
In Figure 4, the phase is $-110^{\circ}$ when the gain reaches 0 dB , giving a phase margin of $70^{\circ}$. The crossover frequency is 20 kHz .

Table 3. Bode Plot Parameters

| PARAMETER | VALUE | UNITS | COMMENT |
| :--- | :---: | :---: | :--- |
| $\mathrm{R}_{\mathrm{L}}$ | 3.3 | $\Omega$ | Application Specific |
| $\mathrm{C}_{\text {OUT }}$ | 94 | $\mu \mathrm{~F}$ | Application Specific |
| $\mathrm{R}_{\text {ESR }}$ | 1 | $\mathrm{~m} \Omega$ | Application Specific |
| $\mathrm{R}_{0}$ | 1.35 | $\mathrm{M} \Omega$ | Not Adjustable |
| $\mathrm{C}_{\mathrm{C}}$ | 1 | nF | Not Adjustable |
| $\mathrm{C}_{\mathrm{F}}$ | 10 | pF | Not Adjustable |
| $\mathrm{C}_{\mathrm{PL}}$ | 0 | pF | Optional/Adjustable |
| $\mathrm{R}_{\mathrm{C}}$ | 155 | $\mathrm{k} \Omega$ | Not Adjustable |
| $\mathrm{R}_{\mathrm{A}}$ | 319 | $\mathrm{k} \Omega$ | Adjustable |
| $\mathrm{R}_{\mathrm{B}}$ | 59 | $\mathrm{k} \Omega$ | Adjustable |
| $\mathrm{V}_{\text {OUT }}$ | 5 | V | Application Specific |
| $\mathrm{V}_{\text {IN }}$ | 12 | V | Application Specific |
| $\mathrm{g}_{\mathrm{ma}}$ | 70 | $\mu \mathrm{mho}$ | Not Adjustable |
| $\mathrm{g}_{\mathrm{mp}}$ | 7.3 | mho | Not Adjustable |
| L | 10 | $\mu \mathrm{H}$ | Application Specific |
| $\mathrm{f}_{\mathrm{S}}$ | 0.45 | MHz | Adjustable |

The previous discussion is a good start for narrowing down the range of component values so that the overall design meets the stability requirements. To obtain good stability margin and transient response, some fine tuning of the external components, i.e., the inductor and output capacitor may be necessary.

## Diode Selection (Primary Channels)

Schottky diodes, with their low forward-voltage drops and fast switching speeds, are recommended for use with the LT8471. Each of the primary channels need an external diode as the second switch. The diode conducts current only during the switch off-time. The average forward current in normal operation can be calculated from:

$$
I_{D(A V G)}=I_{O U T} \bullet(1-D C)
$$

where $\mathrm{I}_{\text {OUT }}$ is the output load current, and DC is the switch duty cycle in steady state.
Choose a diode rated to handle at least $I_{D(A V G)}$. Diodes with higher current rating should be selected to handle increased current during start-up, load transient and/or output short. Choose a Schottky diode with low parasitic capacitance to reduce reverse current spikes through the power switch of the LT8471. In addition, when operating at high ambient temperatures and with high reverse voltages across the Schottky, choose diodes with lower reverse leakage current to avoid excessive heating in the diode. Table 4 lists several Schottky diodes and their manufacturers.
Table 4. Diode Vendors

## APPLICATIONS INFORMATION

## Skyhook Configuration Requirements

The Skyhook provides the boosted $\mathrm{V}_{\mathrm{IN}}$ voltage required for channels operating in the high side configuration. High side channels have their respective C pin tied to a positive $D C$ voltage supply (usually $V_{C C}$ ) while the respective E pin toggles. The channel's $V_{\text {IN }}$ pin should be at least 2.2V (typical) higher than the respective C pin to provide adequate base drive for the NPN power switch. Internal circuits monitor the voltage difference between $\mathrm{V}_{\text {IN1 }}$ and E1 (and $\mathrm{V}_{\text {IN2 }}$ and E2). If the voltage difference is less than 2.2 V (typical), the power switch will be turned off immediately for that clock cycle. Increasing voltage difference between $V_{\text {IN }}$ and the respective $C$ pin increases power loss and reduces efficiency. $V_{\text {IN }}$ must not be more than 40V higher than the respective $C$ pin for high side configurations. If use of Skyhook channel is not desired, then the boosted $\mathrm{V}_{\text {IN }}$ voltage can instead be provided by an external power supply or by the output of the opposite channel if the voltage is high enough.
The Skyhook output (SHOUT) is regulated to $\sim 4.25 \mathrm{~V}$ above the C2 pin voltage and can be connected to the appropriate $V_{\text {IN }}$ pin(s) as shown in the Typical Applications section. When in use, the Skyhook can only be configured as a boost converter (i.e., as in Figure 1a). Also, since SHOUT is regulated to $\sim 4.25 \mathrm{~V}$ above C 2 , the C 2 pin must be connected to a $D C$ voltage (usually $V_{C C}$ ) and must not be toggling. Because of this requirement, if channel 2 is used while the Skyhook is operating, channel 2 must be in the high side configuration such as buck or single-inductor inverting. If not being used, the Skyhook channel can be disabled by connecting the C3 pin to ground. When the Skyhook channel is disabled $\mathrm{V}_{\text {IN1 }}$ current is reduced.

## Capacitor and Diode Selection (Skyhook)

A low ESR capacitor should be used at the Skyhook output to minimize voltage ripple. Ceramic capacitors make a good choice for this (see the discussion in the Capacitor Selection (Primary Channels) section). The capacitor value can affect stability. Read the upcoming Compensation (Skyhook) section for more information.

For the best noise performance, the Skyhook output capacitor should be connected from SHOUT to GND, and the capacitors should be placed close to the pins ( $\mathrm{V}_{\text {IN1 }}$ or $\mathrm{V}_{\text {IN2 } 2}$ ) that SHOUT is shorted to. The Skyhook output capacitor can also be connected from SHOUT to the C2 pin (usually $\mathrm{V}_{\mathrm{CC}}$ ), as shown in Figure 9 a. By doing this, the output voltage of the Skyhook, or the boosted base drive voltage for the primary channels will have better tracking with the supply voltage of the channel. In addition, the voltage across the capacitor is lower, thus reducing the size and required voltage rating of the capacitor.

The Skyhook has a Schottky diode built on-chip. Nevertheless, an external Schottky diode can be connected from C3 to SHOUT to improve performance when load currents are high. The diode choice can be made based on the discussion in the Diode Selection (Primary Channels) section. The output current ( $l_{\text {OUT }}$ ) for the Skyhook channel can be estimated as:

$$
\mathrm{I}_{\text {OUT }} \cong \frac{\left(\mathrm{V}_{C C}+4.25 \mathrm{~V}\right) \cdot\left(\mathrm{I}_{\text {OUT1 }} \cdot \mathrm{DC}_{1}+\mathrm{I}_{\text {OUT2 }} \cdot \mathrm{DC}_{2}\right)}{\beta \cdot \mathrm{V}_{C C} \cdot \eta}
$$

where:
$V_{C C}=$ Input voltage of the Skyhook.
$I_{\text {OUT1 }}=$ Average output current of channel 1 if $\mathrm{V}_{\text {IN } 1}$ is connected to SHOUT (0 otherwise).
$I_{\text {OUT2 }}=$ Average output current of channel 1 if $\mathrm{V}_{\text {IN2 }}$ is connected to SHOUT (0 otherwise).
DC1 = Duty cycle of channel 1 in steady state.
DC2 $=$ Duty cycle of channel 2 in steady state.
$\eta=$ Power conversion efficiency of the Skyhook (typically 87\%).
$\beta=$ Channel 1/channel 2 power switch beta (typically 35)

## APPLICATIONS INFORMATION

Inductor Selection (Skyhook)
The general guidelines are the same as the ones for primary channels, and can be found in the previous section.

Minimum Inductance: There are three conditions that limit the minimum inductance for the Skyhook boost converter:

1. Provide adequate load current;
2. Avoid excessive power switch current overshoot;
3. Maintain good loop stability (see the subsequent Compensation (Skyhook) section).
Choose an inductance that satisfies the minimum requirements for all three criteria. At least $20 \%$ of additional margin is recommended for the inductance.

Adequate Load Current: Starting by assuming the Skyhook operates in discontinuous mode (DCM), the minimum inductance ( $\left.\mathrm{L}_{\mathrm{DCM}(\mathrm{MIN})}\right)$ to provide adequate load current is:

$$
\mathrm{L}_{\mathrm{DCM}(\mathrm{MIN})}>\frac{\left(\mathrm{I}_{\text {OUT1 }} \bullet \mathrm{DC} 1+\mathrm{I}_{\text {OUT2 }} \bullet \mathrm{DC2}\right) \cdot 4.25 \mathrm{~V} \cdot 2}{35 \cdot \eta \cdot \mathrm{f} \bullet \mathrm{I}_{\mathrm{LIM}}{ }^{2}}
$$

Next, verify if the Skyhook will actually operate in DCM with the following inequality:

$$
\mathrm{I}_{\mathrm{LIM}} \cdot \mathrm{~L}_{\mathrm{DCM}(\mathrm{MIN})} \cdot f \cdot\left(\frac{1}{V_{\mathrm{CC}}}+\frac{1}{4.25 \mathrm{~V}}\right)<1
$$

If this inequality is true, then the Skyhook will operate in DCM, and $I_{D C M(M I N)}$ is the minimum inductance needed to provide adequate load current. Otherwise, the Skyhook will operate in continuous mode (CCM) when providing maximum load current, and the minimum inductance (LCCM(MIN) $)$ needed is:
$\mathrm{L}_{\mathrm{CCM}(\mathrm{MIIN})}>$
$\left.\frac{\mathrm{DC}_{S H} \cdot \mathrm{~V}_{\text {CC }}}{2 \cdot f \cdot\left(\mathrm{l}_{\mathrm{LIM}}-\frac{\left(\mathrm{V}_{\text {CC }}+4.25 \mathrm{~V}\right) \cdot\left(\mathrm{l}_{\text {OUT } 1} \cdot \mathrm{DC1}+\mathrm{I}_{\text {OUT2 }} \cdot \mathrm{DC} 2\right)}{}\right)} 35 \cdot \mathrm{~V}_{\text {CC }} \bullet \eta\right)$,
where:
$D C_{S H}=$ Skyhook duty cycle in steady state:

$$
D C_{S H} \cong \frac{4.25 \mathrm{~V}+\mathrm{V}_{\mathrm{DSH}}}{\mathrm{~V}_{\mathrm{C} 2}+4.25 \mathrm{~V}+\mathrm{V}_{\mathrm{DSH}}}
$$

$V_{\text {DSH }}=$ Skyhook diode forward voltage drop (see the Electrical Characteristics section).
$V_{C C}=$ Input voltage of the Skyhook.
$I_{\text {LIM }}=$ Skyhook switch fault current limit, typically 500 mA .
$I_{\text {OUT1 }}=$ Average output current of channel 1 if $\mathrm{V}_{\text {IN1 }}$ is connected to SHOUT (0 otherwise).
$\mathrm{I}_{\text {OUT2 }}=$ Average output current of channel 2 if $\mathrm{V}_{\text {IN2 }}$ is connected to SHOUT (0 otherwise).

DC1 = Duty cycle of channel 1 in steady state.
DC2 $=$ Duty cycle of channel 2 in steady state.
$\eta=$ Power conversion efficiency of Skyhook (typically 87\%).
$f=$ Switching frequency.
Skyhook Power Switch Current Overshoot: In order to avoid excessive current overshoot in the Skyhook power switch, $\mathrm{L}_{\mathrm{OS}(\text { MIN })}$ should be:

where:
$V_{C C}=$ Input voltage of the Skyhook.
$t_{D}=$ Skyhook fault current limit comparator delay (typically 50 ns ).
$\mathrm{I}_{0 S}=$ The amount of overshoot current that can be tolerated (typically 100 mA ).

Current Rating: The maximum switch current limit for the Skyhook is 500 mA . Choose an inductor that has a saturation current of 500 mA or higher to avoid saturating the inductor.

## APPLICATIONS INFORMATION

## Compensation (Skyhook)

Like the primary channels, the Skyhook is internally compensated, and the loop stability is adjusted through the inductor and the output capacitor. In most applications, a $15 \mu \mathrm{H}$ Skyhook inductor such as Würth 744025150. and a $0.47 \mu \mathrm{~F}$ Skyhook output capacitor (C3 in the Block Diagram) will give good stability. For high input voltage applications, more inductance is typically required to reduce the current overshoot.

A good technique to compensate the Skyhook regulator is to start with a $15 \mu \mathrm{H}$ Skyhook inductor and a $0.47 \mu \mathrm{~F}$ output capacitor (C3 in the Block Diagram), and use the subsequent list to make additional adjustments if needed.
More output capacitance (C3 in the Block Diagram) can help with:

- Reducing the SHOUT overshoot and undershoot during primary channel(s) load steps.
Less output capacitance (C3 in the Block Diagram) can help with:
- Improving loop stability.
- Reducing peak inductor current during start-up.

More Skyhook inductance can help with:

- Reducing peak inductor current.

Less Skyhook inductance can help with:

- Improving loop stability when the SHOUT currentload is consistently high (i.e., the primary channel(s) powered by SHOUT is switching every cycle).
Adding a resistor between SHOUT and C2, to introduce a few mA of constant load, can help with:
- Improving the loop stability, SHOUT undershoot and overshoot when the SHOUT current load is consistently very light (i.e., the primary channel(s) powered by SHOUT is not switching every cycle).

## Thermal Considerations

For the LT8471 to deliver its full output power, it is imperative that a good thermal path be provided to dissipate the heat generated within the package. This can be accomplished by taking advantage of the thermal pad on the underside of the IC. It is recommended that multiple vias in the printed circuit board be used to conduct heat away from the IC and into a copper plane with as much area as possible.

Table 5. LT8471 Power Dissipation

| DEFINITION OF VARIABLES | EQUATIONS | DESIGN EXAMPLE | VALUE |
| :---: | :---: | :---: | :---: |
| DC = Switch Duty Cycle | $D C=\frac{V_{\text {OUT }}-V_{\text {IN }}+V_{D}}{V_{\text {OUT }}+V_{D}-V_{\text {CESAT }}}$ | $D C=\frac{12 \mathrm{~V}-5 \mathrm{~V}+0.45 \mathrm{~V}}{12 \mathrm{~V}+0.45 \mathrm{~V}-0.21 \mathrm{~V}}$ | DC = 60.9\% |

## APPLICATIONS INFORMATION

## Power and Thermal Calculations

Power dissipation in the LT8471 chip comes from four primary sources: switch $I^{2}$ R losses, switch dynamic losses, NPN base drive DC losses, and miscellaneous input current losses. These formulas assume continuous mode operation, so they should not be used for calculating thermal losses or efficiency in discontinuous mode or at light load currents.

The following example calculates the power dissipation in the LT8471 for a particular boost application on both CH 1 and $\mathrm{CH} 2\left(\mathrm{~V}_{\text {IN }}=5 \mathrm{~V}, \mathrm{~V}_{\text {OUT }}=12 \mathrm{~V}, \mathrm{I}_{\text {OUT }}=0.67 \mathrm{~A}, \mathrm{f}_{\text {OSC }}\right.$ $=1 \mathrm{MHz}, \mathrm{V}_{\mathrm{D}}=0.45 \mathrm{~V}, \mathrm{~V}_{\text {CESAT }}=0.21 \mathrm{~V}$ ).

To calculate die junction temperature, use the appropriate thermal resistance number and add in worst-case ambient temperature:

$$
\mathrm{T}_{\mathrm{J}}=\mathrm{T}_{\mathrm{A}}+\theta_{\mathrm{JA}} \bullet \mathrm{P}_{\mathrm{TOTAL}}
$$

where $T_{j}=$ Die Junction Temperature, $T_{A}=$ Ambient Temperature, $\mathrm{P}_{\text {TOTAL }}$ is the final result from the calculations shown in Table 5, and $\theta_{\mathrm{JA}}$ is the thermal resistance from the silicon junction to the ambient air.

The $\theta_{\text {ja }}$ value is $38^{\circ} \mathrm{C} / \mathrm{W}$ for the 20 -lead TSSOP package and $44^{\circ} \mathrm{C} / \mathrm{W}$ for the 28 -lead ( $4 \mathrm{~mm} \times 5 \mathrm{~mm}$ ) QFN package. In practice, lower $\theta_{\mathrm{JA}}$ values can be realized if board layout is performed with appropriate grounding (accounting for heat sinking properties of the board) and other considerations listed in the Layout Guidelines section.

## Thermal Lockout

A fault condition occurs when the die temperature exceeds $164^{\circ} \mathrm{C}$ (see Operation Section), and the part goes into thermal lockout. The fault condition ceases when the die temperature drops by $\sim 1.5^{\circ} \mathrm{C}$ (nominal).

## $V_{\text {IN }}$ Ramp Rate

While initially powering a switching converter application, the $\mathrm{V}_{\text {IN }}$ ramp rate should be limited. High $\mathrm{V}_{\text {IN }}$ ramp rates can cause excessive inrush currents in the passive components of the converter. This can lead to current and/or voltage
overstress and may damage the passive components or the chip. Ramp rates less than $500 \mathrm{mV} / \mu \mathrm{s}$, depending on component parameters, will generally prevent these issues. Also, be careful to avoid hot-plugging. Hot-plugging occurs when an active voltage supply is "instantly" connected or switched to the input of the converter. Hot-plugging results in very fast input ramp rates and is not recommended. Finally, for more information, refer to Linear application note AN88, which discusses voltage overstress that can occur when an inductive source impedance is hot-plugged to an input pin bypassed by ceramic capacitors.

## Layout Guidelines

As with all high frequency switchers, when considering layout, care must be taken to achieve optimal electrical, thermal and noise performance. One will not get advertised performance with a careless layout. To prevent noise, both radiated and conducted, the high speed switching current paths must be kept as short as possible. For each channel, the high speed switching current flows in a loop through the following components:

- Boost: NPN power switch (C-E pins), external Schottky diode and output capacitor
- Buck: NPN power switch (C-E pins), external Schottky diode and input capacitor
- 1L Inverting: NPN power switch (C-E pins), external Schottky diode, input capacitor and output capacitor

The area inside the loop formed by these components should be kept as small as possible. This is implemented in the suggested layouts shown in Figure 5, Figure 6 and Figure 7. Shortening the loop will also reduce the parasitic trace inductance. As the NPN switch turns off, the parasitic inductance can produce a flyback spike across the LT8471 switch. When operating at higher currents and output voltages, with poor layout, the spike can generate voltages across the switch that may exceed its absolute maximum rating. A ground plane should also be used under the switcher circuitry to prevent interplane coupling and overall noise. However, there should be no ground plane under the planes that are connected to

## APPLICATIONS INFORMATION

the switching pins to keep the stray capacitance on the switching pins small.
Board layout also has a significant effect on thermal resistance. The exposed package ground pad is the copper plate that runs underthe LT8471 die. This is a good thermal path for conducting heat out of the package. Soldering the
pad onto the board reduces die temperature and increases the power capability of the LT8471. Provide as much copper area as possible around this pad. Adding multiple feedthroughs around the pad to the ground plane will also help. Figure 5, Figure 6, Figure 7 and Figure 8 show the recommended component placement for various DC/DC converter topologies.

Figure 12. Boost Converter with 24V Output and Buck Converter with 5V Output at 550kHz

## PACKAGE DESCRIPTION

Please refer to http://www.linear.com/designtools/packaging/ for the most recent package drawings.

## FE Package

20-Lead Plastic TSSOP (4.4mm)
(Reference LTC DWG \# 05-08-1663 Rev J)
Exposed Pad Variation CB

## PACKAGE DESCRIPTION

Please refer to http://www.linear.com/designtools/packaging/ for the most recent package drawings.

UFD Package
28-Lead Plastic QFN ( $4 \mathrm{~mm} \times 5 \mathrm{~mm}$ )
(Reference LTC DWG \# 05-08-1712 Rev B)

## REVISION HISTORY

| REV | DATE | DESCRIPTION | PAGE NUMBER |
| :---: | :---: | :---: | :---: |
| A | 06/14 | Clarified Applications Information Clarified Typical Applications | $\begin{gathered} 14 \\ 28,29,30,31,34 \end{gathered}$ |
| B | 08/14 | Clarified Operation Paragraph <br> Clarified Applications Information 2nd Paragraph Clarified Typical Application | $\begin{gathered} \hline 9 \\ 10 \\ 34 \end{gathered}$ |
| C | 05/15 | Added H-Grade Option | 2, 3, 4 |
| D | 09/15 | Added QFN Package Option <br> Added Zeta Configuration in Skyhook Channel Description <br> Clarified Voltages to 1.4 V <br> Clarified Figure to 9A on Start-Up Sequencing Description <br> Clarified Figure to 11A on Start-Up Sequencing Description <br> Clarified Figure to 9A on Capacitor and Diode Selection Description <br> Added QFN $\theta_{J A}$ <br> Clarified Figure 5 (for TSSOP Package) added Reference to Figure 8 <br> Clarified Figure 5 (for TSSOP Package) <br> Clarified Figure 5 (for TSSOP Package) <br> Added Figure 8 <br> Relabeled Figures to 9A, 9B, 9C <br> Relabeled Figures to 10A, 10B, 10C, 10D <br> Relabeled Figures to 11A, 11B, 11C, 11D <br> Relabeled Figures to 12 <br> Added QFN Package Drawing <br> Relocated TSSOP Package Drawing <br> Was Page 34-Now Page 36 | $\begin{gathered} \hline 1,2 \\ 9 \\ 12 \\ 14 \\ 20 \\ 21 \\ 24 \\ 25 \\ 26 \\ 27 \\ 28 \\ 29 \\ 30 \\ 31 \\ 32 \\ 34 \\ 33 \\ 36 \end{gathered}$ |

## TYPICAL APPLICATION

## 500kHz ZETA and 2L Inverting Converters Generates $\pm 5 \mathrm{~V}$ Outputs with Low Output Ripple

## Efficiency and Power Loss <br> $V_{C C}=12 V$, with Load Current from $V_{\text {OUT2 }}$ to $V_{\text {OUT1 }}$

Output Voltage Ripple in CCM, $\mathrm{V}_{\text {CC }}=10 \mathrm{~V}$
