

10MHz, Rail-to-Rail Input and Output Op Amp in SOT-23

FEATURES

- Rail-to-Rail Input and Output
- Small SOT-23 Package
- Gain Bandwidth Product: 10MHz
- -40°C to 85°C Operation
- Slew Rate: 2.25V/ μs
- Low Input Offset Voltage: 1.5mV Max
- High Output Current: 25mA Min
- Specified on 3V, 5V and $\pm 5\text{V}$ Supplies
- High Voltage Gain: 1000V/mV 10k Load
- High CMRR: 96dB Typ
- High PSRR: 90dB Typ
- Input Bias Current: 300nA Max
- Input Offset Current: 25nA Max
- 5-Lead SOT-23 Package

APPLICATIONS

- Portable Instrumentation
- Rail-to-Rail Buffer Amplifiers
- Low Voltage Signal Processing
- Driving A/D Converters
- Battery-Powered Systems

DESCRIPTION

The LT[®]1797 is a unity-gain stable 10MHz op amp available in the small SOT-23 package that operates on all single and split supplies with a total voltage of 2.7V to 12V. The amplifier draws 1mA of quiescent current and has a slew rate of 2.25V/ μs .

The input common mode range of the LT1797 includes both rails, making it ideal for current sensing applications. The input stage incorporates phase reversal protection to prevent false outputs from occurring when the inputs are driven beyond the supplies. Protective resistors are included in the input leads so that current does not become excessive when the inputs are forced above or below the supplies.

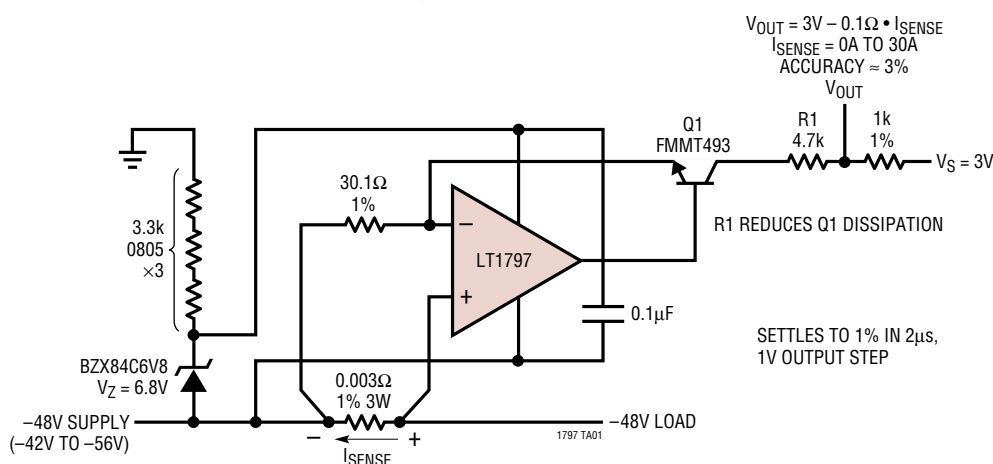

The output of the LT1797 can swing to within 50mV of V^+ and 8mV of V^- without drawing excess current in either condition. The amplifier can drive loads up to 25mA and still maintain rail-to-rail capability.

The LT1797 op amp is available in the space saving 5-lead SOT-23 package.

Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

Note 2: A heat sink may be required to keep the junction temperature below absolute maximum.

Note 3: The LT1797C is guaranteed to meet 0°C to 70°C specifications and is designed, characterized and expected to meet the extended temperature limits, but is not tested at -40°C and 85°C . The LT1797I is guaranteed to meet specified performance from -40°C to 85°C .

Note 4: This parameter is not 100% tested.

Note 5: $V_S = 3\text{V}$ limit guaranteed by correlation to 5V tests.

Note 6: Full-power bandwidth is calculated from the slew rate:

$$\text{FPBW} = \text{SR} / 2\pi V_P$$

APPLICATIONS INFORMATION

Supply Voltage

The positive supply pin of the LT1797 should be bypassed with a small capacitor (about $0.1\mu\text{F}$) within an inch of the pin. When driving heavy loads an additional $4.7\mu\text{F}$ electrolytic capacitor should be used. When using split supplies the same is true for the negative supply pin.

Inputs

The LT1797 is fully functional for an input signal range from the negative supply to the positive supply. Figure 1 shows a simplified schematic of the amplifier. The input stage consists of two differential amplifiers, a PNP stage Q3/Q4 and an NPN stage Q1/Q2 that are active over different ranges of input common mode voltage. The PNP differential pair is active for input common mode voltages V_{CM} between the negative supply to approximately 1.3V below the positive supply. As V_{CM} moves closer toward the positive supply, the transistor QB1 will steer the tail current I1 to the current mirror Q5/Q6, activating the NPN differential pair and the PNP pair becomes inactive for the rest of the input common mode range up to the positive supply.

The input offset voltage and the input bias current are dependent on which input stage is active. The input offset voltage is trimmed on a single 5V supply with the common mode at $1/2$ supply and is typically 1mV with the PNP stage active. The input offset of the NPN stage is untrimmed and is typically 1.5mV . The input bias current polarity depends on the input common mode voltage. When the PNP differential pair is active, the input bias currents flow out of the input pins. They flow in the opposite direction when the NPN input stage is active. The offset error due to the input bias currents can be minimized by equalizing the noninverting and inverting source impedance.

The input stage of the LT1797 incorporates phase reversal protection to prevent false outputs from occurring when the inputs are driven up to 5V beyond the rails. Protective resistors are included in the input leads so that current does not become excessive when the inputs are forced beyond the supplies or when a large differential signal is applied.

Output

The output is configured with a pair of complementary common emitter stages Q19/Q20, which enable the output to swing from rail-to-rail. The output voltage swing of the LT1797 is affected by input overdrive as shown in the Typical Performance Characteristics. When monitoring input voltages within 50mV of V^+ or within 8mV of V^- , some gain should be taken to keep the output from clipping. The output of the LT1797 can deliver large load currents; the short-circuit current limit is typically 50mA at $\pm 5\text{V}$. Take care to keep the junction temperature of the IC below the absolute maximum rating of 150°C . The output of the amplifier has reverse biased diodes to each supply. If the output is forced beyond either supply, unlimited current will flow through these diodes.

The LT1797 can drive capacitive loads up to 200pF on a single 5V supply in a unity gain configuration. When there is a need to drive larger capacitive loads, a resistor of a couple hundred ohms should be connected between the output and the capacitive load. The feedback should still be taken from the output so that the resistor isolates the capacitive load to ensure stability. The low input bias current of the LT1797 makes it possible to use high value feedback resistors to set the gain. However, care must be taken to insure that the pole formed by the feedback resistors and the total capacitance at the inverting input does not degrade stability.

APPLICATIONS INFORMATION

Distortion

There are two main contributors to distortion in op amps: output crossover distortion as the output transitions from sourcing to sinking current and distortion caused by nonlinear common mode rejection. If the op amp is operating in the inverting mode, there is no common mode induced distortion. If the op amp is operating in the PNP input stage (input is not within 1.3V of V^+), the CMRR is very good,

typically 96dB. When the LT1797 switches between input stages there is significant nonlinearity in the CMRR. Lower load resistance increases the output crossover distortion, but has no effect on the input stage transition distortion. For lowest distortion the LT1797 should be operated single supply, with the output always sourcing current and with the input voltage swing between ground and ($V^+ - 1.3V$). See the Typical Performance Characteristic curves.
