## FEATURES

SNR = 57 dB @ 39 MHz Analog Input ( -0.5 dBFS )
Low Power
190 mW at 65 MSPS
285 mW at 105 MSPS
30 mW Power-Down Mode
300 MHz Analog Bandwidth
On-Chip Reference and Track/Hold
1 V p-p or 2 V p-p Analog Input Range Option
Single 3.3 V Supply Operation (2.7 V-3.6 V)
Two's Complement or Offset Binary Data Format Option

## APPLICATIONS

Battery-Powered Instruments
Hand-Held Scopemeters
Low-Cost Digital Oscilloscopes
Ultrasound Equipment
Cable Reverse Path
Broadband Wireless
Residential Power Line Networks

## PRODUCT DESCRIPTION

The AD9214 is a 10 -bit monolithic sampling analog-to-digital converter (ADC) with an on-chip track-and-hold circuit, and is optimized for low cost, low power, small size, and ease of use. The product operates up to 105 MSPS conversion rate with outstanding dynamic performance over its full operating range.
The ADC requires only a single $3.3 \mathrm{~V}(2.7 \mathrm{~V}$ to 3.6 V$)$ power supply and an encode clock for full performance operation. No external reference or driver components are required for many applications. The digital outputs are TTL/CMOS compatible and a separate output power supply pin supports interfacing with 3.3 V or 2.5 V logic.

The clock input is TTL/CMOS compatible. In the power-down state, the power is reduced to 30 mW . A gain option allows support for either 1 V p-p or 2 V p-p analog signal input swing.
Fabricated on an advanced CMOS process, the AD9214 is available in a 28 -lead surface-mount plastic package ( 28 -SSOP) specified over the industrial temperature range $\left(-40^{\circ} \mathrm{C}\right.$ to $\left.+85^{\circ} \mathrm{C}\right)$.

## PRODUCT HIGHLIGHTS

High Performance-Outstanding ac performance from 65 MSPS to 105 MSPS. SNR greater than 55 dB typical and as high as 58 dB .

Low Power-The AD9214 at 285 mW consumes a fraction of the power available in existing high-speed monolithic solutions. In sleep mode, power is reduced to 30 mW .

Single Supply-The AD9214 uses a single 3 V supply, simplifying system power supply design. It also features a separate digital output driver supply line to accommodate 2.5 V logic families.

Small Package-The AD9214 is packaged in a small 28-lead surface-mount plastic package (28-SSOP).

## AD9214-SPECIFICATIONS

DC SPECIFICATIONS $\quad\left(A V_{D D}=3 \mathrm{~V}, \mathrm{DrV}_{D D}=3 \mathrm{~V} ; \mathrm{T}_{\text {MN }}=-40^{\circ} \mathrm{C}, \mathrm{T}_{\text {max }}=+85^{\circ} \mathrm{C}\right.$; external 1.25 V voltage reference and rated encode frequency used, unless otherwise noted.)

## NOTES

${ }^{1}$ Gain error and gain temperature coefficient are based on the ADC only (with a fixed 1.25 V external reference).
${ }^{2}$ Measured with $1 \mathrm{~V} \mathrm{~A}_{\text {IN }}$ range for AD9214-80 and AD9214-105. Measured with $2 \mathrm{~V} \mathrm{~A}_{\mathrm{IN}}$ range for AD9214-65.
${ }^{3}$ REFSENSE externally connected to AGND, REF is configured as an output for the internal reference voltage.
${ }^{4}$ REFSENSE externally connected to $\mathrm{AV}_{\mathrm{DD}}$, REF is configured as an input for an external reference voltage.
${ }^{5} 10 \mathrm{k} \Omega$ to $\mathrm{AV}_{\mathrm{DD}} / 3$ on each input.
${ }^{6} \mathrm{I}_{\text {AVDD }}$ is measured with an analog input of $10.3 \mathrm{MHz}, 0.5 \mathrm{dBFS}$, sine wave, rated encode rate, and PWRDN $=0$. See Typical Performance Characteristics and Applications section for $\mathrm{I}_{\text {DrVDD }}$.
${ }^{7}$ Power-down supply currents measured with $\operatorname{PWRDN}=1$; rated encode rate, $\mathrm{A}_{\text {IN }}=$ full-scale dc input.
${ }^{8}$ Power consumption measured with $\mathrm{A}_{\text {IN }}=$ full-scale dc input.
Specifications subject to change without notice.

## EXPLANATION OF TEST LEVELS

I $100 \%$ production tested.
II $100 \%$ production tested at $25^{\circ} \mathrm{C}$ and guaranteed by design and characterization at specified temperatures.
III Sample Tested Only
IV Parameter is guaranteed by design and characterization testing.
V Parameter is a typical value only.
VI $100 \%$ production tested at $25^{\circ} \mathrm{C}$ and guaranteed by design and characterization for industrial temperature range.

## ORDERING GUIDE

| AD9214BRS-80 | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ (Ambient) | 28-Lead Shrink Small Outline Package | RS-28 |
| AD9214BRS-105 | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ (Ambient) | 28-Lead Shrink Small Outline Package | RS-28 |
| AD9214-65PCB | $25^{\circ} \mathrm{C}$ | Evaluation Board with AD9214-65 |  |
| AD9214-105PCB | $25^{\circ} \mathrm{C}$ | Evaluation Board with AD9214-105 |  |

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD9214 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high-energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## PIN FUNCTION DESCRIPTIONS

| Pin No. | Mnemonic | Function |
| :---: | :---: | :---: |
| 1 | OR | CMOS Output; Out-of-Range Indicator. Logic HIGH indicates the analog input voltage was outside the converter's range for the current output data. |
| 2 | DFS/GAIN | Data Format Select and Gain Mode Select. Connect externally to $A V_{D D}$ for two's complement data format and 1 V p-p analog input range. Connect externally to AGND for Offset Binary data format and 1 V p-p analog input range. Connect externally to REF (Pin 4) for two's complement data format and 2 V p-p analog input range. Floating this pin will configure the device for Offset Binary data format and a 2 V p-p analog input range. |
| 3 | REFSENSE | Reference Mode Select Pin for the ADC. This pin is normally connected externally to AGND, which enables the internal 1.25 V reference, and configures REF (Pin 4) as an analog reference output pin. Connecting REFSENSE externally to $A V_{D D}$ disables the internal reference, and configures REF (Pin 4) as an external reference input. In this case, the user must drive REF with a clean and accurate $1.25 \mathrm{~V}( \pm 5 \%)$ reference input. |
| 4 | REF | Reference input or output as configured by REFSENSE (Pin 3). When configured as an output (REFSENSE = AGND), the internal reference (nominally 1.25 V ) is enabled and is available to the user on this pin. When configured as an input (REFSENSE $=A V_{D D}$ ), the user must drive REF with a clean and accurate $1.25 \mathrm{~V}( \pm 5 \%)$ reference. This pin should be bypassed to AGND with an external $0.1 \mu \mathrm{~F}$ capacitor, whether it is configured as an input or output. |
| 5, 8, 11 | AGND | Analog Ground |
| 6, 7, 12 | $\mathrm{AV}_{\mathrm{DD}}$ | Analog Power Supply, Nominally 3 V |
| 9 | $\mathrm{A}_{\text {IN }}$ | Positive terminal of the differential analog input for the ADC. |

REV. D

## TERMINOLOGY

## Analog Bandwidth

The analog input frequency at which the spectral power of the fundamental frequency (as determined by the FFT analysis) is reduced by 3 dB .

## Aperture Delay

The delay between the $50 \%$ point of the rising edge of the ENCODE command and the instant at which the analog input is sampled.

## Aperture Uncertainty (Jitter)

The sample-to-sample variation in aperture delay.
Differential Analog Input Resistance, Differential Analog Input Capacitance and Differential Analog Input Impedance The real and complex impedances measured at each analog input port. The resistance is measured statically and the capacitance and differential input impedances are measured with a network analyzer.

## Differential Analog Input Voltage Range

The peak-to-peak differential voltage that must be applied to the converter to generate a full-scale response. Peak differential voltage is computed by observing the voltage on a single pin and subtracting the voltage from the other pin, which is 180 degrees out of phase. Peak-to-peak differential is computed by rotating the inputs phase 180 degrees and taking the peak measurement again. Then the difference is computed between both peak measurements.

## Differential Nonlinearity

The deviation of any code width from an ideal 1 LSB step.

## Effective Number of Bits

The effective number of bits (ENOB) is calculated from the measured SNR based on the equation:

$$
E N O B=\frac{\text { SINAD } D_{\text {MEASURED }}-1.76 d B+20 \log \left(\frac{\text { Full Scale }}{\text { Actual }}\right)}{6.02}
$$

## Encode Pulsewidth/Duty Cycle

Pulsewidth high is the minimum amount of time that the ENCODE pulse should be left in Logic " 1 " state to achieve rated performance; pulsewidth low is the minimum time ENCODE pulse should be left in low state. See timing implications of changing $t_{\text {ENCH }}$ in text. At a given clock rate, these specs define an acceptable Encode duty cycle.

## Full-Scale Input Power

Expressed in dBm . Computed using the following equation:

$$
\text { Power }_{\text {FULL SCALE }}=10 \log \left(\frac{\frac{V^{2} \text { FULL SCALE rms }}{}}{Z_{\text {INPUT }}} 0.001\right)
$$

## Gain Error

Gain error is the difference between the measured and ideal full scale input voltage range of the ADC.

## Harmonic Distortion, Second

The ratio of the rms signal amplitude to the rms value of the second harmonic component, reported in dBc .

## Harmonic Distortion, Third

The ratio of the rms signal amplitude to the rms value of the third harmonic component, reported in dBc .

## Integral Nonlinearity

The deviation of the transfer function from a reference line measured in fractions of 1 LSB using a "best straight line" determined by a least square curve fit.

## Minimum Conversion Rate

The encode rate at which the SNR of the lowest analog signal frequency drops by no more than 3 dB below the guaranteed limit.

## Maximum Conversion Rate

The encode rate at which parametric testing is performed.
Output Propagation Delay
The delay between a differential crossing of ENCODE and ENCODE and the time when all output data bits are within valid logic levels.
Noise (for any range within the ADC)

$$
V_{\text {NOISE }}=\sqrt{Z \times 0.001 \times 10 \frac{F S_{d B m}-S N R_{d B c}-\text { Signal }_{d B F S}}{10}}
$$

Where $Z$ is the input impedance, $F S$ is the full-scale of the device for the frequency in question, $S N R$ is the value for the particular input level and Signal is the signal level within the ADC reported in dB below full-scale. This value includes both thermal and quantization noise.

## Power Supply Rejection Ratio (PSRR)

The ratio of a change in input offset voltage to a change in power supply voltage.

## Signal-to-Noise-and-Distortion (SINAD)

The ratio of the rms signal amplitude (set 0.5 dB below full scale) to the rms value of the sum of all other spectral components, including harmonics but excluding dc.

## Signal-to-Noise Ratio (without Harmonics)

The ratio of the rms signal amplitude (set at 0.5 dB below full scale) to the rms value of the sum of all other spectral components, excluding the first five harmonics and dc.

## Spurious-Free Dynamic Range (SFDR)

The ratio of the rms signal amplitude to the rms value of the peak spurious spectral component. The peak spurious component may or may not be a harmonic. May be reported in dBc (i.e., degrades as signal level is lowered), or dBFS (always related back to converter full scale).

## Two-Tone Intermodulation Distortion Rejection

The ratio of the rms value of either input tone to the rms value of the worst third order intermodulation product; reported in dBc .

## Two-Tone SFDR

The ratio of the rms value of either input tone to the rms value of the peak spurious component. The peak spurious component may or may not be an intermodulation distortion product. May be reported in dBc (i.e., degrades as signal level is lowered), or in dBFS (always related back to converter full scale).

## Worst Other Spur

The ratio of the rms signal amplitude to the rms value of the worst spurious component (excluding the second and third harmonic) reported in dBc .

## Transient Response Time

Transient response is defined as the time it takes for the ADC to reacquire the analog input after a transient from $10 \%$ above negative full scale to $10 \%$ below positive full scale.

## Out-of-Range Recovery Time

Out-of-range recovery time is the time it takes for the ADC to reacquire the analog input after a transient from $10 \%$ above positive full scale to $10 \%$ above negative full scale, or from $10 \%$ below negative full scale to $10 \%$ below positive full scale.

## AD9214

## THEORY OF OPERATION

The AD9214 architecture is a bit-per-stage pipeline converter utilizing switch capacitor techniques. These stages determine the 7 MSBs and drive a 3-bit flash. Each stage provides sufficient overlap and error correction allowing optimization of comparator accuracy. The input buffer is differential and both inputs are internally biased. This allows the most flexible use of ac or dc and differential or single-ended input modes. The output staging block aligns the data, carries out the error correction and feeds the data to output buffers. The output buffers are powered from a separate supply, allowing support of different logic families. During power-down, the outputs go to a high impedance state.

## APPLYING THE AD9214

## Encoding the AD9214

Any high-speed A/D converter is extremely sensitive to the quality of the sampling clock provided by the user. A Track/ Hold circuit is essentially a mixer. Any noise, distortion, or timing jitter on the clock will be combined with the desired signal at the A/D output. For that reason, considerable care has been taken in the design of the ENCODE input of the AD9214, and the user is advised to give commensurate thought to the clock
source. The ENCODE input is fully TTL/CMOS compatible, and should normally be driven directly from a low jitter, crystalcontrolled TTL/CMOS oscillator.

The ENCODE input is internally biased, allowing the user to ac-couple in the clock signal. The cleanest clock source is often a crystal oscillator producing a pure sine wave. Figure 7 illustrates ac coupling such a source to the ENCODE input.

Figure 7. AC-Coupled Encode Circuit

## Reference Circuit

The reference circuit of the AD9214 is configured by REFSENSE (Pin 3). By externally connecting REFSENSE to AGND, the ADC is configured to use the internal reference ( $\sim 1.25 \mathrm{~V}$ ), and the REF pin connection (Pin 4) is configured as an output for the internal reference voltage.
If REFSENSE is externally connected to $A V_{D D}$, the $A D C$ is configured to use an external reference. In this mode, the REF pin is configured as a reference input, and must be driven by an external 1.25 V reference.
In either configuration, the analog input voltage range (either 1 V p-p or 2 V p-p as determined by DFS/Gain) will track the reference voltage linearly, and an external bypass capacitor should be connected between REF and AGND to reduce noise on the reference. In practice, no appreciable degradation in performance occurs when an external reference is adjusted $\pm 5 \%$.

## DFS/GAIN

The DFS/GAIN (Data Format Select/Gain) input (Pin 2) controls both the output data format and gain (analog input voltage range) of the ADC. The table below describes its operation.

Table I. Data Format and Gain Configuration

| External <br> DFS/GAIN <br> Connection | Differential <br> Analog Input <br> Voltage Range | Output Data Format |
| :--- | :--- | :--- |
| AGND | 1 V p-p | Offset Binary |
| AV | 1 VD p-p | Two's Complement |
| REF | $2 \mathrm{~V} \mathrm{p-p}$ | Two's Complement |
| Floating | $2 \mathrm{~V} \mathrm{p-p}$ | Offset Binary |

## Driving the Analog Inputs

The analog input to the AD9214 is a differential buffer. As shown in the equivalent circuits, each of the differential inputs is internally dc biased at $\sim \mathrm{AV}_{\mathrm{DD}} / 3$ to allow ac-coupling of the analog input signal. The analog signal may be dc-coupled as well. In this case, the dc load will be equivalent to $\sim 10 \mathrm{k} \Omega$ to $\mathrm{AV}_{\mathrm{DD}} / 3$, and the dc common-mode level of the analog signals should be within the range of $\mathrm{AV}_{\mathrm{DD}} / 3 \pm 200 \mathrm{mV}$. For best dynamic performance, impedances at $\mathrm{A}_{\mathrm{IN}}$ and $\overline{\mathrm{A}_{\mathrm{IN}}}$ should match.
Driving the analog input differentially optimizes ac performance, minimizing even order harmonics and taking advantage of common-mode rejection of noise. A differential signal may be transformer-coupled, as illustrated in Figure 8, or driven from a high-performance differential amplifier such as the AD8138 illustrated in Figure 9.

Figure 8. Single-Ended-to-Differential Conversion Using a Transformer
Special care was taken in the design of the analog input section of the AD9214 to prevent damage and corruption of data when the input is overdriven. The optimal input range is 1.0 V p-p, but the AD9214 can support a 2.0 V p-p input range with some degradation in performance (see DFS/GAIN pin description above).

Figure 9. DC-Coupled Analog Input Circuit

## POWER SUPPLIES

The AD9214 has two power supplies, $\mathrm{AV}_{\mathrm{DD}}$ and $\mathrm{Dr}_{\mathrm{DD}} . \mathrm{AV}_{\mathrm{DD}}$ and AGND supply power to all the analog circuitry, the inputs and the internal timing and digital error correction circuits.
$\mathrm{AV}_{\mathrm{DD}}$ supply current will vary slightly with encode rate, as noted in the Typical Performance Characteristics section.
$\operatorname{Dr} V_{D D}$ and DGND supply only the CMOS digital outputs, allowing the user to adjust the voltage level to match downstream logic.
$\mathrm{Dr} V_{\mathrm{DD}}$ current will vary depending on the voltage level, external loading capacitance, and the encode frequency. Designs that minimize external load capacitance will reduce power consumption and reduce supply noise that may affect ADC performance. The maximum $\mathrm{DrV}_{\mathrm{DD}}$ current can be calculated as

$$
I_{D r V_{D D}}=V_{D r V_{D D}} \times C_{L O A D} \times \text { fencode } \times N
$$

where $N$ is the number of output bits, 10 in the case of the AD9214. This maximum current is for the condition of every output bit switching on every clock cycle, which can only occur for a full scale square wave at the Nyquist frequency, $\mathrm{f}_{\mathrm{ENCODE}} / 2$. In practice, $\mathrm{I}_{\mathrm{Dr}} \mathrm{V}_{\mathrm{DD}}$ will be the average number of output bits switching, which will be determined by the encode rate and the characteristics of the analog input signal. The performance curves section provides a reference of $\mathrm{I}_{\mathrm{Dr} \mathrm{V}_{\mathrm{DD}}}$ versus encode rate for a 10.3 MHz sine wave driving the analog input.
Both power supply connections should be decoupled to ground at or near the package connections, using high quality, ceramic chip capacitors. A single ground plane is recommended for all ground (AGND and DGND) connections.
The PWRDN control pin configures the AD9214 for a sleep mode when it is logic HIGH. PWRDN floats logic LOW for normal operation. In sleep mode, the ADC is not active, and will consume less power. When switching from sleep mode to normal operation, the ADC will need $\sim 15$ clock cycles to recover to valid output data.

## Digital Outputs

Care must be taken when designing the data receivers for the AD9214. It is recommended that the digital outputs drive a series resistor (e.g., $100 \Omega$ ) followed by a gate like the 74LCX821. To minimize capacitive loading, there should be only one gate on each output pin. An example of this is shown in the evaluation board schematic in Figure 10. The series resistors should be placed as close to the AD9214 as possible to limit the amount of current that can flow into the output stage. These switching currents are confined between ground (DGND) and the $\mathrm{DrV}_{\mathrm{DD}}$ pins. Standard TTL gates should be avoided since they can appreciably add to the dynamic switching currents of the AD9214.

It should also be noted that extra capacitive loading will increase output timing and invalidate timing specifications. Digital output timing is guaranteed with 10 pF loads.

## LAYOUT INFORMATION

The schematic of the evaluation board (Figure 10) represents a typical implementation of the AD9214. A multilayer board is recommended to achieve best results. It is highly recommended that high quality, ceramic chip capacitors be used to decouple each supply pin to ground directly at the device. The pinout of the AD9214 facilitates ease of use in the implementation of high frequency, high resolution design practices. All of the digital outputs and their supply and ground pin connections are segregated to one side of the package, with the inputs on the opposite side for isolation purposes.
Care should be taken when routing the digital output traces. To prevent coupling through the digital outputs into the analog portion of the AD9214, minimal capacitive loading should be placed on these outputs. It is recommended that a fan-out of only one gate should be used for all AD9214 digital outputs.
The layout of the encode circuit is equally critical. Any noise received on this circuitry will result in corruption in the digitization process and lower overall performance. The Encode clock must be isolated from the digital outputs and the analog inputs.

## EVALUATION BOARD

The AD9214 evaluation board offers designers an easy way to evaluate device performance. The user must supply an analog input signal, encode clock reference, and power supplies. The digital outputs of the AD9214 are latched on the evaluation board, and are available with a data ready signal at a 40 -pin edge connector. Please refer to the evaluation board schematic, layout, and Bill of Materials.

## Power Connections

Power to the board is supplied via three detachable, 4-pin power strips (U4, U9, and U10). These 12 pins should be driven as outlined in the Table II.

Table II. Power Supply Connections for AD9214 Evaluation Board

| Pin | Designator | External Supply <br> Required |
| :--- | :--- | :--- |
| 1 | LVC | 3 V |
| 3 | +5 V | +5 V |
|  |  | $($ Optional Z1 Supply) |
| 5 | -5 V | -5 V |
| 7 |  | $($ Optional Z1 Supply) |
| 9 | VCC | 3 V |
| 11 | VDD | 3 V |
| $2,4,6$, | DAC | 5 V |
| $8,10,12$ | GND | Ground |

Please note that the +5 V and -5 V supplies are optional, and only required if the user adds differential op amp Z1 to the board.

## Reference Circuit

The evaluation board is configured at assembly to use the AD9214's on-board reference. To supply an external reference, the user must connect the REFSENSE pin to VCC by removing the jumper block connecting E25 to E26, and placing it between E19 and E24. In this configuration, an external 1.25 V reference must be connected to jumper connection E23. Jumper connections E19-E21, E24, and resistors R13-R14 are omitted at assembly, and not used in the evaluation of the AD9214.

## Gain/Data Format

The evaluation board is assembled with the DFS/GAIN pin connected to ground; this configures the AD9214 for a 1 V p-p analog input range, and offset binary data format. The user may remove this jumper and replace it to make one of the connections described in the table below to configure the AD9214 for different gain and output data format options.

Table III. Data Format and Gain Configuration for Evaluation Board

| DFS/GAIN <br> Jumper <br> Placement | DFS/GAIN <br> Connection | Differential $A_{\text {IN }}$ Range | Output Data Format |
| :---: | :---: | :---: | :---: |
| E18 to E12 | AGND | 1 V p-p | Offset Binary |
| E16 to E11 | $\mathrm{AV}_{\mathrm{DD}}$ | 1 Vp -p | Two's Complement |
| E15 to E14 | REF | 2 Vp -p | Two's Complement |
| E17 to E13 | Floating | 2 V p-p | Offset Binary |

## Power-Down

The evaluation board is configured at assembly so that the PWRDN input floats low for normal operating condition. The user may add a jumper between option holes E5 and E6 to connect PWRDN to AVCC, configuring the AD9214 for powerdown mode.

## Encode Signal and Distribution

The encode input signal should drive SMB connector J5, which has an on-board $50 \Omega$ termination. A standard CMOS compatible pulse source is recommended. Alternatively, the user can adjust the dc level of an ac-coupled clock source by adding resistor R11, normally omitted. J5 drives the AD9214 ENCODE input and one gate of U12, which buffers and distributes the clock signal to the on-board latch (U3), the reconstruction DAC (U11), and the output data connector (U2). The board comes assembled with timing options optimized for the DAC and latch; the user may invert the DR signal at Pin 37 of edge connector U2 by removing the jumper block between E34 and E35, and reinstalling it between E35 and E36.

## Analog Input

The analog input signal is connected to the evaluation board by SMB connector J1. As configured at assembly, the signal is ac coupled by capacitor C10 to transformer T1. This $1: 1$ transformer provides a $50 \Omega$ termination for connector J1 via $25 \Omega$ resistors R1 and R4. T1 also converts the signal at J1 into a differential signal for the analog inputs of the AD9214. Resistor R3, normally omitted, can be used to terminate J1 if the transformer is removed.
The user can reconfigure the board to drive the AD9214 singleendedly by removing the jumper block between E1 and E3, and replacing it between E3 and E2. In this configuration, capacitor C 2 stabilizes the self-bias of $\overline{\mathrm{A}_{\mathrm{IN}}}$, and resistor R 2 provides a matched impedance for a $50 \Omega$ source at J1.
Transformer T1 can be bypassed by moving the jumper normally between E40 and E38 to connect E40 to E37, and moving the jumper normally between E39 and E10 to connect E7 to E10. In this configuration, the analog input of the AD 9214 is driven single ended, directly from J1; and R3 (normally omitted) should be installed to terminate any cable connected to J1.

## Using the AD8138

An optional driver circuit for the analog input, based on the AD8138 differential amplifier, is included in the layout of the AD9214 evaluation board. This portion of the evaluation circuit is not populated when the board is manufactured, but can be easily be added by the user. Resistors R5, R16, R18, and R25 are the feedback network that sets the gain of the AD8138. Resistors R23 and R24 set the common-mode voltage at the output of the op amp. Resistors R27 and R28, and capacitor C15, form a low-pass filter at the output of the AD8138, limiting its noise contribution into the AD9214.
Once the drive circuit is populated, the user should remove the jumper block normally between E40 and E38, and place it between E 40 and E 41 . This will ac-couple the analog input signal from SMB connector J1 to the AD8138 drive circuit. The user will also need to remove the jumper blocks that normally connect E39 to E10 and E1 to E3 to remove transformer T1 from the circuit.

## DAC Reconstruction Circuit

The data available at output connector U 2 is also reconstructed by DAC U11, the AD9752. This 12-bit, high-speed digital-to-analog converter is included as a tool in setting up and debugging the evaluation board. It should not be used to measure the performance of the AD9214, as its performance will not accurately reflect the performance of the ADC. The DAC's output, available at J2, will drive $50 \Omega$. The user can add a jumper block between E8 and E9 to activate the SLEEP function of the DAC.
