## FEATURES

2-channel 12-bit DAC
Twos complement facilitates bipolar applications
Bipolar zero with 2 V dc offset
Built-in $\mathbf{2 . 0 0 0}$ V precision reference with $10 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ typ TC
Buffered voltage output: 0 V to 4 V
Single-supply operation: 4.5 V to 5.5 V
Fast $0.8 \mu$ settling time typ
Ultracompact MSOP-10 package
Monotonic DNL < $\pm 1$ LSB
Optimized accuracy at zero scale
Power-on reset to $V_{\text {REF }}$
3-wire serial data input
Extended temperature range: $-\mathbf{4 0}{ }^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$

## APPLICATIONS

Single-supply bipolar converter operations
General-purpose DSP applications
Digital gain and offset controls
Instrumentation level settings
Disk drive control
Precision motor control

## GENERAL DESCRIPTION

The AD5399 is the industry-first dual 12-bit digital-to-analog converter that accepts twos complement digital coding with 2 V dc offset for single-supply operation. Augmented with a built-in precision reference and a solid buffer amplifier, the AD5399 is the smallest self-contained 12-bit precision DAC that fits many general-purpose as well as DSP specific applications. The twos complement programming facilitates the natural coding implementation commonly found in DSP applications, and allows operation in single supply. The AD5399 provides a 2 V reference output, $\mathrm{V}_{\text {REF }}$, for bipolar zero monitoring. It can also be used for other on-board components that require a precision reference. The device is specified for operation from $5 \mathrm{~V} \pm 10 \%$ single supply with bipolar output swing from 0 V to 4 V centered at 2 V .

The AD5399 is available in the compact 1.1 mm low profile MSOP-10 package. All parts are guaranteed to operate over the extended industrial temperature range of $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$. registered trademarks are the property of their respective owners.

## ABSOLUTE MAXIMUM RATINGS

$\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise noted.
Table 3.

| Parameter | Rating |
| :---: | :---: |
| $V_{\text {DD }}$ to GND | -0.3 V, +7.5 V |
| Vouta, $\mathrm{V}_{\text {outb, }} \mathrm{V}_{\text {bz }}$ to GND | $0 \mathrm{~V}, \mathrm{~V}_{\mathrm{DD}}$ |
| Digital Input Voltages to GND | $0 \mathrm{~V}, \mathrm{~V} D+0.3 \mathrm{~V}$ |
| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$ |
| Maximum Junction Temperature ( $\mathrm{T}_{\text {max }}$ ) | $150^{\circ} \mathrm{C}$ |
| Storage Temperature | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Lead Temperature (Soldering, 10 sec ) | $300^{\circ} \mathrm{C}$ |
| Package Power Dissipation | $\left(\mathrm{T}_{\text {Jmax }}-\mathrm{T}_{\mathrm{A}}\right.$ ) $/ \theta_{\text {JA }}$ |
| Thermal Resistance, $\theta_{\mathrm{JA}}$, MSOP-10 | $206^{\circ} \mathrm{C} / \mathrm{W}$ |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 3. MSOP-10 Pin Configuration

Table 4. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 1 | CLK | Serial Clock Input. Positive edge triggered. |
| 2 | SDI | Serial Data Input. MSB first format. |
| 3 | DGND | Digital Ground. |
| 4 | Vоитв | DAC B Voltage Output ( $\mathrm{A}=$ Logic 1 ). |
| 5 | Vouta | DAC A Voltage Output ( $\mathrm{A} 0=$ Logic 0 ). |
| 6 | $V_{B Z}$ | 2 V , Virtual Bipolar Zero (Active Output). |
| 7 | AGND | Analog Ground. |
| 8 | $V_{\text {DD }}$ | Positive Power Supply. Specified for operation at 5 V . |
| 9 | $\mathrm{V}_{\text {TP }}$ | Connect to $V_{\text {DD. }}$. Reserved for factory testing. |
| 10 | $\overline{C S}$ | Chip Select (Frame Sync Input). Allows clock and data to shift into the shift register when $\overline{\mathrm{CS}}$ goes from high to low. After the $16^{\text {th }}$ clock pulse, it is not necessary to bring $\overline{\mathrm{CS}}$ high to shift the data to the output. However, $\overline{\mathrm{CS}}$ should be brought high any time after the 16th clock positive edge in order to allow the next programming cycle. |

## OPERATION

The AD5399 provides a 12-bit, twos complement, dual voltage output, digital-to-analog converter (DAC). It has an internal reference with 2 V bipolar zero dc offset, where $0 \leq \mathrm{V}_{\text {out }} \leq 4 \mathrm{~V}$.

The output transfer equation is

$$
V_{\text {OUT }}=((D-2048) / 4096 \times 4 \mathrm{~V})+2 \mathrm{~V}
$$

where:
$D$ is the 12-bit decimal code and not the twos complement code. Vout is with respect to ground.

In data programming, the data is loaded MSB first on the positive clock edge (SCLK) after chip select $(\overline{\mathrm{CS}})$ goes from high to low. The digital word is 16 bits wide, with the MSB, B15, as an address bit (DAC A: A $0=0 ; \mathrm{DAC} \mathrm{B}: \mathrm{A} 0=1$ ). B 14 is don't care, B13 is a shutdown bit, B12 must be logic low, and the last 12 bits are data bits. An internal counter allows data transferred from the shift register to the output after the $16^{\text {th }}$ positive clock edge while $\overline{\mathrm{CS}}$ stays low (see Figure 5). After the $16^{\text {th }}$ clock pulse, it is not necessary to bring $\overline{\mathrm{CS}}$ high to shift the data to the output. However, $\overline{\mathrm{CS}}$ should be brought high anytime after the 16th clock positive edge in order to allow the next programming cycle.

Table 6. Input Logic Control Truth Table

| CLK | $\overline{\text { CS }}$ | Register Activity |
| :--- | :--- | :--- |
| L | H | No Shift Register Effect |
| H | H | No Shift Register Effect |
| P | L | Shift One SDI Bit into the SR <br> $16^{\text {th }}$ P |
| L | Transfer SR Data into DAC Register and Update <br> the Output |  |

$\mathrm{P}=$ Positive Edge, $\mathrm{X}=$ Don't Care, $\mathrm{SR}=$ Shift Register.

The data setup and data hold times in the Specifications table determine the timing requirements. The internal power-on reset circuit clears the serial input registers to all 0 s , and sets the two DAC registers to a $V_{B Z}$ (zero code) of 2 V .

Software shutdown B13 turns off the internal REF and amplifiers. The output is close to zero potential, and the digital circuitry remains active such that new data can be written. Therefore, the DAC register is refreshed with the new data once the shutdown bit is deactivated.

All digital inputs are ESD protected with a series input resistor and parallel Zener, as shown in Figure 21, that apply to digital input pins CLK, SDA, and $\overline{\mathrm{CS}}$. The basic connection is shown in Figure 22.

Figure 21. Equivalent ESD Protection Circuit

Figure 22. Basic Connection

## POWER-UP/POWER-DOWN SEQUENCE

Like most CMOS devices, it is recommended to power $V_{D D}$ and ground prior to any digital signals. The ideal power-up sequence is $G N D, V_{D D}$, and digital signals. The reverse sequence applies to the power-down condition.

## Layout and Power Supply Bypassing

It is a good practice to employ compact, minimum lead-length layout design. The input leads should be as direct as possible with a minimum conductor length. Ground paths should have low resistance and low inductance.

Similarly, it is also good practice to bypass the power supplies with quality capacitors for optimum stability. Supply leads to the device should be bypassed with $0.01 \mu \mathrm{~F}$ to $0.1 \mu \mathrm{~F}$ disc or chip ceramic capacitors. Low ESR $1 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F}$ tantalum or electrolytic capacitors should also be applied at $V_{D D}$ to minimize any transient disturbance and to filter any low frequency ripple (see Figure 23). Users should not apply switching regulators for $V_{D D}$ due to the power supply rejection ratio degradation over frequency.

Figure 23. Power Supply Bypassing and Grounding Connection

## Grounding

The DGND and AGND pins of the AD5399 refer to the digital and analog ground references. To minimize the digital ground bounce, the DGND terminal should be joined remotely at a single point to the analog ground plane, as shown in Figure 23.

## Shutdown Function

The AD5399 shutdown function allows both DACs to be shutdown simultaneously. However, the A0 and SD bits work in tandem, and the A0 logic state must be the same for shutdown activation and deactivation (see Table 7).

Table 7. Shutdown Activation and Deactivation Sequence.

| Sequence <br> of Events | Data-Word <br> in Binary | Shutdown Status |
| :--- | :--- | :--- |
| 1 | OX10 XXXX <br> XXXX XXXX <br> 1 1X00 XXXX <br> XXXX XXXX <br> OX00 XXXX <br> XXXX XXXX | Activate shutdown on both DACs. <br> 3 |
| The A0 bit (MSB) must be in the same state when activating and deactivating <br> resume normal operation. |  |  |

For users whose logic signals may be in three-state (random levels) during power-up initialization, it is recommended to put a pull-up resistor at the $\overline{\mathrm{CS}}$ pin to disable chip select (Figure 24). This avoids inadvertent shutdown as well as the inability to deactivate shutdown due to an unknown A0 state. The resistor value depends on the digital controller's output impedance.

Figure 24. Disable $\overline{C S}$ for Random Logic Mode

[^0]:    ${ }^{1}$ Typical values represent average readings at $25^{\circ} \mathrm{C}$ and $\mathrm{V}_{D D}=5 \mathrm{~V}$.
    ${ }^{2}$ Guaranteed by design and not subject to production test.
    ${ }^{3} \mathrm{P}_{\text {DISs }}$ is calculated from ( $\mathrm{l}_{D D} \times \mathrm{V}_{D D}$ ). CMOS logic level inputs result in minimum power dissipation.
    ${ }^{4}$ See timing diagram (Figure5) for location of measured values. All input control voltages are specified with $t_{R}=t_{F}=2 \mathrm{~ns}(10 \%$ to $90 \%$ of 3 V ) and timed from a voltage level of 1.5 V . Switching characteristics are measured using $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}$. Input logic should have a $1 \mathrm{~V} / \mu \mathrm{s}$ minimum slew rate.
