## TDA1085C

## Universal Motor Speed Controller

The TDA1085C is a phase angle triac controller having all the necessary functions for universal motor speed control in washing machines. It operates in closed loop configuration and provides two ramp possibilities.

## Features

- On-Chip Frequency to Voltage Converter
- On-Chip Ramps Generator
- Soft-Start
- Load Current Limitation
- Tachogenerator Circuit Sensing
- Direct Supply from AC Line
- Security Functions Performed by Monitor
- Pb -Free Package is Available*

## GENERAL DESCRIPTION

The TDA 1085C triggers a triac accordingly to the speed regulation requirements. Motor speed is digitally sensed by a tachogenerator and then converted into an analog voltage.

The speed set is externally fixed and is applied to the internal linear regulation input after having been submitted to programmable acceleration ramps. The overall result
consists in a full motor speed range with two acceleration ramps which allow efficient washing machine control (Distribute function).
Additionally, the TDA 1085C protects the whole system against AC line stop or variations, overcurrent in the motor and tachogenerator failure.

## INPUT/OUTPUT FUNCTIONS

(Refer to Figures 1 and 8)

## Voltage Regulator (Pins 9 and 10)

This is a parallel type regulator able to sink a large amount of current and offering good characteristics. Current flow is provided from AC line by external dropping resistors R1, R2, and rectifier: This half wave current is used to feed a smothering capacitor, the voltage of which is checked by the IC.

When $\mathrm{V}_{\mathrm{CC}}$ is reached, the excess of current is derived by another dropping resistor R10 and by Pin 10. These three resistors must be determined in order:

- To let 1.0 mA flow through Pin 10 when AC line is minimum and $\mathrm{V}_{\mathrm{CC}}$ consumption is maximum (fast ramps and pulses present).
- To let $\mathrm{V}_{10}$ reach 3.0 V when AC line provides maximum current and $\mathrm{V}_{\mathrm{CC}}$ consumption is minimum (no ramps and no pulses).
- All along the main line cycle, the Pin 10 dynamic range must not be exceeded unless loss of regulation.
An AC line supply failure would cause shut down.
The double capacitive filter built with R1 and R2 gives an efficient $\mathrm{V}_{\mathrm{CC}}$ smoothing and helps to remove noise from set speeds.

## Speed Sensing (Pins 4, 11, 12)

The IC is compatible with an external analog speed sensing: its output must be applied to Pin 4, and Pin 12 connected to Pin 8.

In most of the applications it is more convenient to use a digital speed sensing with an inexpensive tachogenerator which doesn't need any tuning. During every positive cycle at Pin 12, the capacitor $C_{\text {Pin }} 11$ is charged to almost $\mathrm{V}_{\mathrm{CC}}$ and during this time, Pin 4 delivers a current which is 10 times the one charging $\mathrm{C}_{\text {Pin }} 11$. The current source gain is called G and is tightly specified, but nevertheless requires an adjustment on $\mathrm{R}_{\text {Pin 4. }}$. The current into this resistor is proportional to $\mathrm{C}_{\text {Pin }} 11$ and to the motor speed; being filtered by a capacitor, $\mathrm{V}_{\text {Pin }} 4$ becomes smothered and represents the "true actual motor speed".

To maintain linearity into the high speed range, it is important to verify that $\mathrm{C}_{\mathrm{Pin}} 11$ is fully charged: the internal source on Pin 11 has $100 \mathrm{~K} \Omega$ impedance. Nevertheless $C_{\text {Pin } 11}$ has to be as high as possible as it has a large influence on FV/C temperature factor. A $470 \mathrm{~K} \Omega$ resistor between Pins 11 and 9 reduces leakage
currents and temperature factor as well, down to neglectable effects.
Pin 12 also has a monitoring function: when its voltage is above 5.0 V , the trigger pulses are inhibited and the IC is reset. It also senses the tachogenerator continuity, and in case of any circuit aperture, it inhibits pulse, avoiding the motor to run out of control. In the TDA 1085C, Pin 12 is negatively clamped by an internal diode which removes the necessity of the external one used in the former circuit.

## Ramp Generator (Pins 5, 6, 7)

The true Set Speed value taken in consideration by the regulation is the output of the ramp generator (Pin 7). With a given value of speed set input (Pin 5), the ramp generator charges an external capacitor $\mathrm{C}_{\text {Pin } 7}$ up to the moment $\mathrm{V}_{\text {Pin }} 5$ (set speed) equals $V_{\text {Pin }} 4$ (true speed), see Figure 2. The IC has an internal charging current source of 1.2 mA and delivers it from 0 to 12 V at Pin 7. It is the high acceleration ramp ( 5.0 s typical) which allows rapid motor speed changes without excessive strains on the mechanics. In addition, the TDA 1085C offers the possibility to break this high acceleration with the introduction of a low acceleration ramp (called Distribution) by reducing the Pin 7 source current down to $5.0 \mu \mathrm{~A}$ under Pin 6 full control, as shown by following conditions:

- Presence of high acceleration ramp $V_{\text {Pin } 5}>V_{\text {Pin }}$
- Distribution occurs in the $V_{\text {Pin }} 4$ range (true motor
speed) defined by $\mathrm{V}_{\text {Pin } 6} \leqq \mathrm{~V}_{\text {Pin } 4} \leqq 2.0 \mathrm{~V}_{\text {Pin } 6}$
For two fixed values of $V_{\operatorname{Pin} 5}$ and $V_{\operatorname{Pin} 6}$, the motor speed will have high acceleration, excluding the time for $V_{\text {Pin }} 4$ to go from $\mathrm{V}_{\text {Pin }} 6$ to two times this value, high acceleration again, up to the moment the motor has reached the set speed value, at which it will stay, see Figure 3.
Should a reset happen (whatever the cause would be), the above mentioned successive ramps will be fully reprocessed from 0 to the maximum speed. If $\mathrm{V}_{\text {Pin } 6}=0$, only the high acceleration ramp occurs.

To get a real zero speed position, Pin 5 has been designed in such a way that its voltage from 0 to 80 mV is interpreted as a true zero. As a consequence, when changing the speed set position, the designer must be sure that any transient zero would not occur: if any, the entire circuit will be reset.

As the voltages applied by Pins 5 and 6 are derived from the internal voltage regulator supply and Pin 4 voltage is also derived from the same source, motor speed (which is determined by the ratios between above mentioned voltages) is totally independent from $\mathrm{V}_{\mathrm{CC}}$ variations and temperature factor.

## Control Amplifier (Pin 16)

It amplifies the difference between true speed (Pin 4) and set speed (Pin 5), through the ramp generator. Its output available at Pin 16 is a double sense current source with a maximum capability of $\pm 100 \mu \mathrm{~A}$ and a specified transconductance ( $340 \mu \mathrm{~A} / \mathrm{V}$ typical). Pin 16 drives directly the trigger pulse generator, and must be loaded by an electrical network which compensates the mechanical characteristics of the motor and its load, in order to provide stability in any condition and shortest transient response; see Figure 4.

This network must be adjusted experimentally.
In case of a periodic torque variations, Pin 16 directly provides the phase angle oscillations.

Trigger Pulse Generator (Pins 1, 2, 5, 13, 14, 15)
This circuit performs four functions:

- The conversion of the control amplifier DC output level to a proportional firing angle at every main line half cycle.
- The calibration of pulse duration.
- The repetition of the pulse if the triac fails to latch on if the current has been interrupted by brush bounce.
- The delay of firing pulse until the current crosses zero at wide firing angles and inductive loads.
$\mathrm{R}_{\text {Pin }} 15$ programs the Pin 14 discharging current. Saw tooth signal is then fully determined by R15 and C14 (usually 47 nF ). Firing pulse duration and repetition period are in inverse ratio to the saw tooth slope.

Pin 13 is the pulse output and an external limiting resistor is mandatory. Maximum current capability is 200 mA .

## Current Limiter (Pin 3)

Safe operation of the motor and triac under all conditions is ensured by limiting the peak current. The motor current develops an alternative voltage in the shunt resistor $(0.05 \Omega$ in Figure 4). The negative half waves are transferred to Pin 3 which is positively preset at a voltage determined by resistors R3 and R4. As motor current increases, the dynamical voltage range of Pin 3 increases and when Pin 3 becomes slightly negative in respect to Pin 8, a current starts to circulate in it. This current, amplified typically 180 times, is then used to discharge Pin 7 capacitor and, as a result, reduces firing angle down to a value where an equilibrium is reached. The choice of resistors R3, R4 and shunt determines the magnitude of the discharge current signals on $C_{\text {Pin }} 7$.

Notice that the current limiter acts only on peak triac current.

## APPLICATION NOTES

## (Refer to Figure 4)

## Printed Circuit Layout Rules

In the common applications, where TDA 1085C is used, there is on the same board, presence of high voltage, high currents as well as low voltage signals where millivolts count. It is of first magnitude importance to separate them from each other and to respect the following rules:

- Capacitor decoupling pins, which are the inputs of the same comparator, must be physically close to the IC, close to each other and grounded in the same point.
- Ground connection for tachogenerator must be directly connected to Pin 8 and should ground only the tacho. In effect, the latter is a first magnitude noise generator due to its proximity to the motor which induces high $\mathrm{d} \phi / \mathrm{dt}$ signals.
- The ground pattern must be in the "star style" in order to fully eliminate power currents flowing in the ground network devoted to capacitors decoupling sensitive Pins: $4,5,7,11,12,14,16$.

As an example, Figure 5 presents a PC board pattern which concerns the group of sensitive Pins and their associated capacitors into which the a.m. rules have been implemented. Notice the full separation of "Signal World" from "Power", one by line AB and their communication by a unique strip.

These rules will lead to much satisfactory volume production in the sense that speed adjustment will stay valid in the entire speed range.

## Power Supply

As dropping resistor dissipates noticeable power, it is necessary to reduce the $\mathrm{I}_{\mathrm{CC}}$ needs down to a minimum. Triggering pulses, if a certain number of repetitions are kept in reserve to cope with motor brush wearing at the end of its life, are the largest $\mathrm{I}_{\mathrm{CC}}$ user. Classical worst case configuration has to be considered to select dropping resistor. In addition, the parallel regulator must be always into its dynamic range, i.e., $I_{\text {Pin }} 10$ over 1.0 mA and $\mathrm{V}_{\text {Pin }} 10$ over 3.0 V in any extreme configuration. The double filtering cell is mandatory.

## Tachogenerator Circuit

The tacho signal voltage is proportional to the motor speed. Stability considerations, in addition, require an RC filter, the pole of which must be looked at. The combination of both elements yield a constant amplitude signal on Pin 12 in most of the speed range. It is recommended to verify this maximum amplitude to be within 1.0 V peak in order to have the largest signal/noise ratio without resetting the integrated circuit (which occurs if $\mathrm{V}_{\text {Pin } 12}$ reaches 5.5 V ). It must be also verified that the Pin 12 signal is approximately balanced between "high" (over 300 mV ) and "low". An 8-poles tacho is a minimum for low speed stability and a 16 -poles is even better.

The RC pole of the tacho circuit should be chosen within 30 Hz in order to be as far as possible from the 150 Hz which corresponds to the AC line 3rd harmonic generated by the motor during starting procedure. In addition, a high value resistor coming from $\mathrm{V}_{\mathrm{CC}}$ introduces a positive offset at Pin 12 , removes noise to be interpreted as a tacho signal. This offset should be designed in order to let Pin 12 reach at least -200 mV (negative voltage) at the lowest motor speed. We remember the necessity of an individual tacho ground connection.

## Frequency to Voltage Converter - F V/C

$\mathrm{C}_{\text {Pin }} 11$ has a recommended value of 820 pF for 8-poles tachos and maximum motor rpm of 15000 , and $\mathrm{R}_{\text {Pin }} 11$ must be always 470 K .
$\mathrm{R}_{\text {Pin } 4}$ should be chosen to deliver within 12 V at maximum motor speed in order to maximize signal/noise ratio. As the $\mathrm{FV} / \mathrm{C}$ ratio as well as the $\mathrm{C}_{\text {Pin } 11}$ value are dispersed, $\mathrm{R}_{\text {Pin } 4}$ must be adjustable and should be made of a fixed resistor in service with a trimmer representing $25 \%$ of the total. Adjustment would become easier.

Once adjusted, for instance at maximum motor speed, the FV/C presents a residual non linearity; the conversion factor ( mV per RPM) increases by within $7.7 \%$ as speed draws to zero. The guaranteed dispersion of the latter being very narrow, a maximum $1 \%$ speed error is guaranteed if during Pin 5 network design the small set values are modified, once forever, according this increase.

The following formulas give $V_{\text {Pin 4 }}$

$$
\begin{aligned}
& \left.V_{\text {Pin } 4}=G .0 \cdot\left(V_{C C}-V_{a}\right) \cdot C_{\text {Pin } 11} \cdot R_{4} \cdot f \cdot{ }_{\left(1+\frac{1}{120 k}\right.}^{R_{\text {Pin } 11}}\right)^{\text {nn volts. }} \\
& G .0 \cdot\left(V_{\mathrm{CC}}-V_{\mathrm{a}}\right)=140 \\
& \left.V_{a}=2.0 V_{B E}\right) \\
& 120 \mathrm{k}=R_{\text {int }} \text { on Pin } 11
\end{aligned}
$$

## Speed Set (Pin 5)

Upon designer choice, a set of external resistors apply a series of various voltages corresponding to the various motor speeds. When switching external resistors, verify that no voltage below 80 mV is ever applied to Pin 5. If so, a full circuit reset will occur.

## Ramps Generator (Pin 6)

If only a high acceleration ramp is needed, connect Pin 6 to ground.
When a Distribute ramp should occur, preset a voltage on Pin 6 which corresponds to the motor speed starting ramp point. Distribution (or low ramp) will continue up to the moment the motor speed would have reached twice the starting value.

The ratio of two is imposed by the IC. Nevertheless, it could be externally changed downwards (Figure 6) or upwards (Figure 7).
The distribution ramp can be shortened by an external resistor from $\mathrm{V}_{\mathrm{CC}}$ charging $\mathrm{C}_{\mathrm{Pin}} 7$, adding its current to the internal $5.0 \mu \mathrm{~A}$ generator.

## Power Circuits

Triac Triggering pulse amplitude must be determined by Pin 13 resistor according to the needs in Quadrant IV. Trigger pulse duration can be disturbed by noise signals generated by the triac itself, which interfere within Pins 14 and 16 , precisely those which determine it. While easily visible, this effect is harmless.
The triac must be protected from high AC line $\mathrm{dV} / \mathrm{dt}$ during external disturbances by $100 \mathrm{nF} \times 100 \Omega$ network.
Shunt resistor must be as non-inductive as possible. It can be made locally by using constantan alloy wire.
When the load is a DC fed universal motor through a rectifier bridge, the triac must be protected from commutating $\mathrm{dV} / \mathrm{dt}$ by a 1.0 to 2.0 mH coil in series with $\mathrm{MT}_{2}$.
Synchronization functions are performed by resistors sensing AC line and triac conduction. 820 k values are normal but could be reduced down to 330 k in order to detect the "zeros" with accuracy and to reduce the residual DC line component below 20 mA .

## Current Limitation

The current limiter starts to discharge Pin 7 capacitor (reference speed) as the motor current reaches the designed threshold level. The loop gain is determined by the resistor connecting Pin 3 to the series shunt. Experience has shown that its optimal value for a 10 Arms limitation is within $2.0 \mathrm{k} \Omega$. Pin 3 input has a sensitivity in current which is limited to reasonable values and should not react to spikes.
If not used, Pin 3 must be connected to a maximum positive voltage of 5.0 V rather than be left open.

## Loop Stability

The Pin 16 network is predominant and must be adjusted experimentally during module development. The values indicated in Figure 4 are typical for washing machine applications but accept large modifications from one model to another. R16 (the sole restriction) should not go below 33 k , otherwise slew rate limitation will cause large transient errors for load steps.

GENERIC MARKING DIAGRAM*

XXXXX = Specific Device Code
A = Assembly Location
WL = Wafer Lot
YY = Year
WW = Work Week
$\mathrm{G} \quad=\mathrm{Pb}-$ Free Package
*This information is generic. Please refer to device data sheet for actual part marking. $\mathrm{Pb}-\mathrm{Free}$ indicator, "G" or microdot " $\mathrm{\bullet}$ ", may or may not be present.

| DESCRIPTION: | PDIP-16 | PAGE 1 OF 1 |

[^1]ON Semiconductor and ON are trademarks of Semiconductor Components Industries, LLC dba ON Semiconductor or its subsidiaries in the United States and/or other countries. ON Semiconductor owns the rights to a number of patents, trademarks, copyrights, trade secrets, and other intellectual property. A listing of ON Semiconductor's product/patent coverage may be accessed at www.onsemi.com/site/pdf/Patent-Marking.pdf. ON Semiconductor reserves the right to make changes without further notice to any products herein. ON Semiconductor makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does ON Semiconductor assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. Buyer is responsible for its products and applications using ON Semiconductor products, including compliance with all laws, regulations and safety requirements or standards, regardless of any support or applications information provided by ON Semiconductor. "Typical" parameters which may be provided in ON Semiconductor data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. ON Semiconductor does not convey any license under its patent rights nor the rights of others. ON Semiconductor products are not designed, intended, or authorized for use as a critical component in life support systems or any FDA Class 3 medical devices or medical devices with a same or similar classification in a foreign jurisdiction or any devices intended for implantation in the human body. Should Buyer purchase or use ON Semiconductor products for any such unintended or unauthorized application, Buyer shall indemnify and hold ON Semiconductor and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that ON Semiconductor was negligent regarding the design or manufacture of the part. ON Semiconductor is an Equal Opportunity/Affirmative Action Employer. This literature is subject to all applicable copyright laws and is not for resale in any manner.
