Please note that Cypress is an Infineon Technologies Company.

The document following this cover page is marked as "Cypress" document as this is the company that originally developed the product. Please note that Infineon will continue to offer the product to new and existing customers as part of the Infineon product portfolio.

Continuity of document content

The fact that Infineon offers the following product as part of the Infineon product portfolio does not lead to any changes to this document. Future revisions will occur when appropriate, and any changes will be set out on the document history page.

Continuity of ordering part numbers

Infineon continues to support existing part numbers. Please continue to use the ordering part numbers listed in the datasheet for ordering.

www.infineon.com

64-Mb (8M × 8-Bit/4M × 16-Bit), 3 V, Simultaneous Read/Write Flash

Distinctive Characteristics

Architectural Advantages

■ Simultaneous Read/Write operations
  – Data can be continuously read from one bank while executing erase/program functions in another bank
  – Zero latency between read and write operations
■ Flexible bank architecture
  – Read may occur in any of the three banks not being programmed or erased
  – Four banks may be grouped by customer to achieve desired bank divisions
■ Boot sectors
  – Top and bottom boot sectors in the same device
  – Any combination of sectors can be erased
■ Manufactured on 0.11 µm Process Technology
■ Secured Silicon Region: **Extra 256-byte sector**
  – *Factory locked and identifiable:* 16 bytes available for secure, random factory Electronic Serial Number; verifiable as factory locked through autoselect function
  – *Customer lockable:* One-time programmable only. Once locked, data cannot be changed
■ Zero power operation
  – Sophisticated power management circuits reduce power consumed during inactive periods to nearly zero
■ Compatible with JEDEC standards
  – Pinout and software compatible with single-power-supply flash standard

Package Options

■ 48-ball Fine-pitch BGA
■ 48-pin TSOP

Performance Characteristics

■ High performance
  – Access time as fast as 55 ns
  – Program time: 7 µs/word typical using accelerated programming function

■ Ultra low power consumption (typical values)
  – 2 mA active read current at 1 MHz
  – 10 mA active read current at 5 MHz
  – 200 nA in standby or automatic sleep mode
■ Cycling endurance: 1 million cycles per sector typical
■ Data retention: 20 years typical

Software Features

■ Supports Common Flash Memory Interface (CFI)
■ Erase suspend/erase resume
  – Suspends erase operations to read data from, or program data to, a sector that is not being erased, then resumes the erase operation
■ Data# polling and toggle bits
  – Provides a software method of detecting the status of program or erase operations
■ Unlock bypass program command
  – Reduces overall programming time when issuing multiple program command sequences

Hardware Features

■ Ready/Busy# output (RY/BY#)
  – Hardware method for detecting program or erase cycle completion
■ Hardware reset pin (RESET#)
  – Hardware method of resetting the internal state machine to the read mode
■ WP#/ACC input pin
  – Write protect (WP#) function protects sectors 0, 1, 140, and 141, regardless of sector protect status
  – Acceleration (ACC) function accelerates program timing
■ Sector Protection
  – Hardware method to prevent any program or erase operation within a sector
  – Temporary Sector Unprotect allows changing data in protected sectors in-system

General Description

The S29JL064J is a 64 Mb, 3.0 volt-only flash memory device, organized as 4,194,304 words of 16 bits each or 8,388,608 bytes of 8 bits each. Word mode data appears on DQ15–DQ0; byte mode data appears on DQ7–DQ0. The device is designed to be programmed in-system with the standard 3.0 volt V_{CC} supply, and can also be programmed in standard EPROM programmers. The device is available with an access time of 55, 60, 70 ns and is offered in a 48-ball FBGA or 48-pin TSOP package. Standard control pins—chip enable (CE#), write enable (WE#), and output enable (OE#)—control normal read and write operations, and avoid bus contention issues. The device requires only a **single 3.0 volt power supply** for both read and write functions. Internally generated and regulated voltages are provided for the program and erase operations.

Contents

1. Simultaneous Read/Write Operations with Zero Latency

The Simultaneous Read/Write architecture provides **simultaneous operation** by dividing the memory space into **four banks,** two 8 Mb banks with small and large sectors, and two 24 Mb banks of large sectors. Sector addresses are fixed, system software can be used to form user-defined bank groups.

During an Erase/Program operation, any of the three non-busy banks may be read from. Note that only two banks can operate simultaneously. The device can improve overall system performance by allowing a host system to program or erase in one bank, then immediately and simultaneously read from the other bank, with zero latency. This releases the system from waiting for the completion of program or erase operations.

The S29JL064J is organized as a dual boot device with both top and bottom boot sectors.

Bank	Mbs	Sector Sizes
Bank 1	8 Mb	Eight 8 KB/4 kword, Fifteen 64 KB/32 kword
Bank 2	24 Mb	Forty-eight 64 KB/32 kword
Bank 3	24 Mb	Forty-eight 64 KB/32 kword
Bank 4	8 Mb	Eight 8 KB/4 kword, Fifteen 64 KB/32 kword

1.1 S29JL064J Features

The **Secured Silicon Region** is an extra 256 byte sector capable of being permanently locked by Cypress or customers. The Secured Silicon Customer Indicator Bit (DQ6) is permanently set to 1 if the part has been customer locked, and permanently set to 0 if the part has been factory locked. This way, customer lockable parts can never be used to replace a factory locked part.

Factory locked parts provide several options. The Secured Silicon Region may store a secure, random 16 byte ESN (Electronic Serial Number), customer code (programmed through Cypress programming services), or both. Customer Lockable parts may utilize the Secured Silicon Region as bonus space, reading and writing like any other flash sector, or may permanently lock their own code there.

The device offers complete compatibility with the **JEDEC 42.4 single-power-supply Flash command set standard**. Commands are written to the command register using standard microprocessor write timings. Reading data out of the device is similar to reading from other Flash or EPROM devices.

The host system can detect whether a program or erase operation is complete by using the device **status bits:** RY/BY# pin, DQ7 (Data# Polling) and DQ6/DQ2 (toggle bits). After a program or erase cycle has been completed, the device automatically returns to the read mode.

The **sector erase architecture** allows memory sectors to be erased and reprogrammed without affecting the data contents of other sectors. The device is fully erased when shipped from the factory.

Hardware data protection measures include a low V_{CC} detector that automatically inhibits write operations during power transitions. The **hardware sector protection** feature disables both program and erase operations in any combination of the sectors of memory. This can be achieved in-system or via programming equipment.

The Erase Suspend/Erase Resume feature enables the user to put erase on hold for any period of time to read data from, or program data to, any sector that is not selected for erasure. True background erase can thus be achieved. If a read is needed from the Secured Silicon Region (One Time Promgram area) after an erase suspend, then the user must use the proper command sequence to enter and exit this region.

The device offers two power-saving features. When addresses have been stable for a specified amount of time, the device enters the **automatic sleep mode**. The system can also place the device into the **standby mode**. Power consumption is greatly reduced in both modes.

2. Product Selector Guide

Part Number		S29JL064J		
Speed Option	Standard Voltage Range: V_{CC} = 2.7–3.6V	55	60	70
Max Access Time (ns), t_{ACC}		55	60	70
CE# Access (ns), t_{CE}		55	60	70

5. Pin Description

Table 1.

|	
A21–A0	22 Address pins
DQ14–DQ0	15 Data Inputs/Outputs (x16-only devices)
DQ15/A-1	DQ15 (Data Input/Output, word mode), A-1 (LSB Address Input, byte mode)
CE#	Chip Enable, Active Low
OE#	Output Enable, Active Low
WE#	Write Enable, Active Low
WP#/ACC	Hardware Write Protect/Acceleration Pin
RESET#	Hardware Reset Pin, Active Low
BYTE#	Selects 8-bit or 16-bit mode, Active Low
RY/BY#	Ready/Busy Output, Active Low
V_{CC}	3.0 volt-only single power supply (see Section 2. Product Selector Guide on page 4 for speed options and voltage supply tolerances)
V_{SS}	Device Ground
NC	Not Connected. No device internal signal is connected to the package connector nor is there any future plan to use the connector for a signal. The connection may safely be used for routing space for a signal on a Printed Circuit Board (PCB).
DNU	Do Not Use. A device internal signal may be connected to the package connector. The connection may be used by Cypress for test or other purposes and is not intended for connection to any host system signal. Any DNU signal related function will be inactive when the signal is at V_{IL}. The signal has an internal pull-down resistor and may be left unconnected in the host system or may be tied to V_{SS}. Do not use these connections for PCB signal routing channels. Do not connect any host system signal to these connections.
RFU	Reserved for Future Use. No device internal signal is currently connected to the package connector but there is potential future use for the connector for a signal. It is recommended to not use RFU connectors for PCB routing channels so that the PCB may take advantage of future enhanced features in compatible footprint devices.

6. Logic Symbol
7. Ordering Information

The order number is formed by a valid combination of the following:

S29JL064J   **55**   **T**   **F**   **I**   **00**   **0**

Packing Type
0 = Tray
3 = 13-inch Tape and Reel

Model Number (Additional Ordering Options)
00 = Standard Configuration

Temperature Range
I = Industrial (–40°C to +85°C)
A = Automotive, AEC-Q100 Grade 3 (-40°C to +85°C)

Package Material Set
F = Pb-free
H = Low-halogen, Pb-free

Package Type
B = Fine-pitch Ball Grid Array (FBGA) Package
T = Thin Small Outline Package (TSOP) Standard Pinout

Speed Option
55 = 55 ns
60 = 60 ns
70 = 70 ns

Product Family
S29JL064J: 3.0 Volt-only, 64 Mb (4 M x 16-bit/8 M x 8-bit) Simultaneous
Read/Write Flash Memory Manufactured on 110 nm process technology

Note
1. Packing type 0 is standard. Specify other options as required.

Valid Combinations — Standard

			S29JL064J Valid Combinations				
Device Number/ Description	Speed (ns)	Package Type and Material	Temperature Range	Model Number	Packing Type	Package Description	
S29JL064J	55, 70	TF	I	00	0, 3[1]	TS048	TSOP
		BH				VBK048	FBGA

Valid Combinations — Automotive Grade / AEC-Q100

The table below lists configurations that are Automotive Grade / AEC-Q100 qualified and are planned to be available in volume. The table will be updated as new combinations are released. Consult your local sales representative to confirm availability of specific combinations and to check on newly released combinations.

Production Part Approval Process (PPAP) support is only provided for AEC-Q100 grade products.

Products to be used in end-use applications that require ISO/TS-16949 compliance must be AEC-Q100 grade products in combination with PPAP. Non–AEC-Q100 grade products are not manufactured or documented in full compliance with ISO/TS-16949 requirements.

AEC-Q100 grade products are also offered without PPAP support for end-use applications that do not require ISO/TS-16949 compliance.

			S29JL064J Valid Combination - Automotive

8. Device Bus Operations

This section describes the requirements and use of the device bus operations, which are initiated through the internal command register. The command register itself does not occupy any addressable memory location. The register is a latch used to store the commands, along with the address and data information needed to execute the command. The contents of the register serve as inputs to the internal state machine. The state machine outputs dictate the function of the device. Table 2 lists the device bus operations, the inputs and control levels they require, and the resulting output. The following subsections describe each of these operations in further detail.

Table 2. S29JL064J Device Bus Operations

Operation	CE#	OE#	WE#	RESET#	WP#/ACC	Addresses[1]	DQ15–DQ8 BYTE# = V_{IH}	DQ15–DQ8 BYTE# = V_{IL}	DQ7–DQ0
Read	L	L	H	H	L/H	A_{IN}	D_{OUT}	DQ14–DQ8 = High-Z, DQ15 = A-1	D_{OUT}
Write	L	H	L	H	Note [3]	A_{IN}	D_{IN}		D_{IN}
Standby	$V_{CC} \pm 0.3V$	X	X	$V_{CC} \pm 0.3V$	L/H	X	High-Z	High-Z	High-Z
Output Disable	L	H	H	H	L/H	X	High-Z	High-Z	High-Z
Reset	X	X	X	L	L/H	X	High-Z	High-Z	High-Z
Sector Protect[2]	L	H	L	V_{ID}	L/H	SA, A6 = L, A1 = H, A0 = L	X	X	D_{IN}
Sector Unprotect[2]	L	H	L	V_{ID}	Note [3]	SA, A6 = H, A1 = H, A0 = L	X	X	D_{IN}
Temporary Sector Unprotect	X	X	X	V_{ID}	Note [3]	A_{IN}	D_{IN}	High-Z	D_{IN}

Legend
L = Logic Low = V_{IL}
H = Logic High = V_{IH}
V_{ID} = 11.5–12.5V
V_{HH} = 9.0 ± 0.5V
X = Don't Care
SA = Sector Address
A_{IN} = Address In
D_{IN} = Data In
D_{OUT} = Data Out

8.1 Word/Byte Configuration

The BYTE# pin controls whether the device data I/O pins operate in the byte or word configuration. If the BYTE# pin is set at logic '1', the device is in word configuration, DQ15–DQ0 are active and controlled by CE# and OE#.

If the BYTE# pin is set at logic '0', the device is in byte configuration, and only data I/O pins DQ7–DQ0 are active and controlled by CE# and OE#. The data I/O pins DQ14–DQ8 are tri-stated, and the DQ15 pin is used as an input for the LSB (A-1) address function.

Notes
2. Addresses are A21:A0 in word mode (BYTE# = V_{IH}), A21:A-1 in byte mode (BYTE# = V_{IL}).
3. The sector protect and sector unprotect functions may also be implemented via programming equipment. See Section 8.10 Boot Sector/Sector Block Protection and Unprotection on page 18.
4. If WP#/ACC = V_{IL}, sectors 0, 1, 140, and 141 remain protected. If WP#/ACC = V_{IH}, protection on sectors 0, 1, 140, and 141 depends on whether they were last protected or unprotected using the method described in Section 8.10 Boot Sector/Sector Block Protection and Unprotection on page 18. If WP#/ACC = V_{HH}, all sectors will be unprotected.

8.2 Requirements for Reading Array Data

To read array data from the outputs, the system must drive the CE# and OE# pins to V_{IL}. CE# is the power control and selects the device. OE# is the output control and gates array data to the output pins. WE# should remain at V_{IH}. The BYTE# pin determines whether the device outputs array data in words or bytes.

The internal state machine is set for reading array data upon device power-up, or after a hardware reset. This ensures that no spurious alteration of the memory content occurs during the power transition. No command is necessary in this mode to obtain array data. Standard microprocessor read cycles that assert valid addresses on the device address inputs produce valid data on the device data outputs. Each bank remains enabled for read access until the command register contents are altered.

Refer to Section 17.1 Read-Only Operations on page 45 for timing specifications and to Figure 16 on page 45 for the timing diagram. I_{CC1} in Section 14. DC Characteristics on page 41 represents the active current specification for reading array data.

8.3 Writing Commands/Command Sequences

To write a command or command sequence (which includes programming data to the device and erasing sectors of memory), the system must drive WE# and CE# to V_{IL}, and OE# to V_{IH}.

For program operations, the BYTE# pin determines whether the device accepts program data in bytes or words. Refer to Section 8.1 Word/Byte Configuration on page 10 for more information.

The device features an **Unlock Bypass** mode to facilitate faster programming. Once a bank enters the Unlock Bypass mode, only two write cycles are required to program a word or byte, instead of four. Section 10.5 Byte/Word Program Command Sequence on page 28 has details on programming data to the device using both standard and Unlock Bypass command sequences.

An erase operation can erase one sector, multiple sectors, or the entire device. Table 4 on page 16 indicates the address space that each sector occupies. Similarly, a *sector address* is the address bits required to uniquely select a sector. Section 10. Command Definitions on page 27 has details on erasing a sector or the entire chip, or suspending/resuming the erase operation.

The device address space is divided into four banks. A *bank address* is the address bits required to uniquely select a bank.

I_{CC2} in the *DC Characteristics on page 41* represents the active current specification for the write mode. Section 17. AC Characteristics on page 45 contains timing specification tables and timing diagrams for write operations.

8.3.1 Accelerated Program Operation

The device offers accelerated program operations through the ACC function. This is one of two functions provided by the WP#/ACC pin. This function is primarily intended to allow faster manufacturing throughput at the factory.

If the system asserts V_{HH} on this pin, the device automatically enters the aforementioned Unlock Bypass mode, temporarily unprotects any protected sectors, and uses the higher voltage on the pin to reduce the time required for program operations. The system would use a two-cycle program command sequence as required by the Unlock Bypass mode. Removing V_{HH} from the WP#/ACC pin returns the device to normal operation. Note that V_{HH} must not be asserted on WP#/ACC for operations other than accelerated programming, or device damage may result. In addition, the WP#/ACC pin must not be left floating or unconnected; inconsistent behavior of the device may result. See *Write Protect (WP#) on page 19* for related information.

8.3.2 Autoselect Functions

If the system writes the autoselect command sequence, the device enters the autoselect mode. The system can then read autoselect codes from the internal register (which is separate from the memory array) on DQ15–DQ0. Standard read cycle timings apply in this mode. Refer to *Autoselect Mode on page 17* and *Autoselect Command Sequence on page 28* for more information.

8.4 Simultaneous Read/Write Operations with Zero Latency

This device is capable of reading data from one bank of memory while programming or erasing in another bank of memory. An erase operation may also be suspended to read from or program to another location within the same bank (except the sector being erased). Figure 23 on page 50 shows how read and write cycles may be initiated for simultaneous operation with zero latency. I_{CC6} and I_{CC7} in the Section 14. DC Characteristics on page 41 represent the current specifications for read-while-program and read-while-erase, respectively.

8.5 Standby Mode

When the system is not reading or writing to the device, it can place the device in the standby mode. In this mode, current consumption is greatly reduced, and the outputs are placed in the high impedance state, independent of the OE# input.

The device enters the CMOS standby mode when the CE# and RESET# pins are both held at $V_{CC} \pm 0.3V$. (Note that this is a more restricted voltage range than V_{IH}.) If CE# and RESET# are held at V_{IH}, but not within $V_{CC} \pm 0.3V$, the device will be in the standby mode, but the standby current will be greater. The device requires standard access time (t_{CE}) for read access when the device is in either of these standby modes, before it is ready to read data.

If the device is deselected during erasure or programming, the device draws active current until the operation is completed.

I_{CC3} in Section 14. DC Characteristics on page 41 represents the standby current specification.

8.6 Automatic Sleep Mode

The automatic sleep mode minimizes Flash device energy consumption. The device automatically enables this mode when addresses remain stable for t_{ACC} + 30 ns. The automatic sleep mode is independent of the CE#, WE#, and OE# control signals. Standard address access timings provide new data when addresses are changed. While in sleep mode, output data is latched and always available to the system. I_{CC5} in Section 14. DC Characteristics on page 41 represents the automatic sleep mode current specification.

8.7 RESET#: Hardware Reset Pin

The RESET# pin provides a hardware method of resetting the device to reading array data. When the RESET# pin is driven low for at least a period of t_{RP}, the device immediately terminates any operation in progress, tristates all output pins, and ignores all read/write commands for the duration of the RESET# pulse. The device also resets the internal state machine to reading array data. The operation that was interrupted should be reinitiated once the device is ready to accept another command sequence, to ensure data integrity.

Current is reduced for the duration of the RESET# pulse. When RESET# is held at $V_{SS} \pm 0.3V$, the device draws CMOS standby current (I_{CC4}). If RESET# is held at V_{IL} but not within $V_{SS} \pm 0.3V$, the standby current will be greater.

The RESET# pin may be tied to the system reset circuitry. A system reset would thus also reset the Flash memory, enabling the system to read the boot-up firmware from the Flash memory.

If RESET# is asserted during a program or erase operation, the RY/BY# pin remains a "0" (busy) until the internal reset operation is complete, which requires a time of t_{READY} (during Embedded Algorithms). The system can thus monitor RY/BY# to determine whether the reset operation is complete. If RESET# is asserted when a program or erase operation is not executing (RY/BY# pin is "1"), the reset operation is completed within a time of t_{READY} (not during Embedded Algorithms). The system can read data t_{RH} after the RESET# pin returns to V_{IH}.

Refer to Section 17.2 Hardware Reset (RESET#) on page 46 for RESET# parameters and to Figure 17 on page 46 for the timing diagram.

8.8 Output Disable Mode

When the OE# input is at V_{IH}, output from the device is disabled. The output pins are placed in the high impedance state.

Table 3. S29JL064J Sector Architecture

1	000
2	001, 010, 011
3	100, 101, 110
4	111

Table 5. Secured Silicon Region Addresses

Device	Sector Size	(x8) Address Range	(x16) Address Range
S29JL064J	256 bytes	000000h–0000FFh	000000h–00007Fh

8.9 Autoselect Mode

The autoselect mode provides manufacturer and device identification, and sector protection verification, through identifier codes output on DQ7–DQ0. This mode is primarily intended for programming equipment to automatically match a device to be programmed with its corresponding programming algorithm. However, the autoselect codes can also be accessed in-system through the command register.

When using programming equipment, the autoselect mode requires V_{ID} on address pin A9. Address pins must be as shown in Table . In addition, when verifying sector protection, the sector address must appear on the appropriate highest order address bits (see Table 4 on page 16). Table shows the remaining address bits that are don't care. When all necessary bits have been set as required, the programming equipment may then read the corresponding identifier code on DQ7–DQ0. However, the autoselect codes can also be accessed in-system through the command register, for instances when the S29JL064J is erased or programmed in a system without access to high voltage on the A9 pin. The command sequence is illustrated in Table 12 on page 32. *Note that if a Bank Address (BA) on address bits A21, A20, and A19 is asserted during the third write cycle of the autoselect command, the host system can read autoselect data from that bank and then immediately read array data from another bank, without exiting the autoselect mode.*

To access the autoselect codes in-system, the host system can issue the autoselect command via the command register, as shown in Table 12 on page 32. This method does not require V_{ID}. Refer to Section 10.3 Autoselect Command Sequence on page 28 for more information.

S29JL064J Autoselect Codes, (High Voltage Method)

Description		CE#	OE#	WE#	A21 to A12	A11 to A10	A9	A8 to A7	A6	A5 to A4	A3	A2	A1	A0	DQ15 to DQ8 BYTE#= V_{IH}	DQ15 to DQ8 BYTE# = V_{IL}	DQ7 to DQ0
Manufacturer ID: Cypress Products		L	L	H	BA	X	V_{ID}	X	L	X	L	L	L	L	X	X	01h
Device ID	Read Cycle 1	L	L	H	BA	X	V_{ID}	X	L	X	L	L	L	H	22h	X	7Eh
Device ID	Read Cycle 2	L	L	H	BA	X	V_{ID}	X	L	X	H	H	H	L	22h	X	02h

Sector Protection Verification		L	L	H	SA	X	V_{ID}	X	L	X	L	L	H	L	X	X	01h (protected), 00h (unprotected)
Secured Silicon Indicator Bit (DQ6, DQ7)		L	L	H	BA	X	V_{ID}	X	L	X	L	L	H	H	X	X	81h (Factory Locked), 41h (Customer Locked), 01h (Not Locked)

Legend

L = Logic Low = V_{IL}

H = Logic High = V_{IH}

BA = Bank Address

SA = Sector Address

X = Don't care.

8.10 Boot Sector/Sector Block Protection and Unprotection

Note: For the following discussion, the term *sector* applies to both boot sectors and sector blocks. A sector block consists of two or more adjacent sectors that are protected or unprotected at the same time (see Table 6).

The hardware sector protection feature disables both program and erase operations in any sector. The hardware sector unprotection feature re-enables both program and erase operations in previously protected sectors. Sector protection/unprotection can be implemented via two methods.

SA119–SA122	11100XXXXX	256 (4x64) KB
SA123–SA126	11101XXXXX	256 (4x64) KB
SA127–SA130	11110XXXXX	256 (4x64) KB
SA131–SA133	1111100XXX, 1111101XXX, 1111110XXX	192 (3x64) KB
SA134	1111111000	8 KB
SA135	1111111001	8 KB
SA136	1111111010	8 KB
SA137	1111111011	8 KB
SA138	1111111100	8 KB
SA139	1111111101	8 KB
SA140	1111111110	8 KB
SA141	1111111111	8 KB

Sector Protect/Sector Unprotect requires V_{ID} on the RESET# pin only, and can be implemented either in-system or via programming equipment. Figure 4 on page 21 shows the algorithms and Figure 28 on page 53 shows the timing diagram. For sector unprotect, all unprotected sectors must first be protected prior to the first sector unprotect write cycle. *Note that the sector unprotect algorithm unprotects all sectors in parallel. All previously protected sectors must be individually re-protected.* To change data in protected sectors efficiently, the temporary sector unprotect function is available. See Section 8.12 Temporary Sector Unprotect on page 20.

The device is shipped with all sectors unprotected. Optional Cypress programming service enable programming and protecting sectors at the factory prior to shipping the device. Contact your local sales office for details.

It is possible to determine whether a sector is protected or unprotected. See Section 8.9 Autoselect Mode on page 17 for details.

8.11   Write Protect (WP#)

The Write Protect function provides a hardware method of protecting without using V_{ID}. This function is one of two provided by the WP#/ACC pin.

If the system asserts V_{IL} on the WP#/ACC pin, the device disables program and erase functions in sectors 0, 1, 140, and 141, independently of whether those sectors were protected or unprotected using the method described in Section 8.10 Boot Sector/Sector Block Protection and Unprotection on page 18.

If the system asserts V_{IH} on the WP#/ACC pin, the device reverts to whether sectors 0, 1, 140, and 141 were last set to be protected or unprotected. That is, sector protection or unprotection for these sectors depends on whether they were last protected or unprotected using the method described in Section 8.10 Boot Sector/Sector Block Protection and Unprotection on page 18.

Note that the WP#/ACC pin must not be left floating or unconnected; inconsistent behavior of the device may result.

Table 7. WP#/ACC Modes

WP# Input Voltage	Device Mode
V_{IL}	Disables programming and erasing in SA0, SA1, SA140, and SA141
V_{IH}	Enables programming and erasing in SA0, SA1, SA140, and SA141, dependent on whether they were last protected or unprotected.
V_{HH}	Enables accelerated programming (ACC). See Section 8.3.1 Accelerated Program Operation on page 11.

8.12   Temporary Sector Unprotect

Note: For the following discussion, the term *sector* applies to both sectors and sector blocks. A sector block consists of two or more adjacent sectors that are protected or unprotected at the same time (see Table 6 on page 18).

This feature allows temporary unprotection of previously protected sectors to change data in-system. The Temporary Sector Unprotect mode is activated by setting the RESET# pin to V_{ID}. During this mode, formerly protected sectors can be programmed or erased by selecting the sector addresses. Once V_{ID} is removed from the RESET# pin, all the previously protected sectors are protected again. Figure 3 shows the algorithm, and Figure 27 on page 52 shows the timing diagrams, for this feature. If the WP#/ACC pin is at V_{IL}, sectors 0, 1, 140, and 141 will remain protected during the Temporary sector Unprotect mode.

Figure 3. Temporary Sector Unprotect Operation
Notes
6. All protected sectors unprotected (If WP#/ACC = V_{IL}, sectors 0, 1, 140, and 141 will remain protected).
7. All previously protected sectors are protected once again.

Figure 4. In-System Sector Protect/Unprotect Algorithms

Figure 4. In-System Sector Protect/Unprotect Algorithms
8.13 Secured Silicon Region

The Secured Silicon Region feature provides a Flash memory region that enables permanent part identification through an Electronic Serial Number (ESN). The Secured Silicon Region is 256 bytes in length, and may shipped unprotected, allowing customers to utilize that sector in any manner they choose, or may shipped locked at the factory (upon customer request). The Secured Silicon Indicator Bit data will be 81h if factory locked, 41h if customer locked, or 01h if neither. Refer to Table on page 17 for more details.

The system accesses the Secured Silicon Region through a command sequence (see Section 10.4 Enter Secured Silicon Region/Exit Secured Silicon Region Command Sequence on page 28). After the system has written the Enter Secured Silicon Region command sequence, it may read the Secured Silicon Region by using the addresses normally occupied by the boot sectors. This mode of operation continues until the system issues the Exit Secured Silicon Region command sequence, or until power is removed from the device. On power-up, or following a hardware reset, the device reverts to sending commands to the first 256 bytes of Sector 0. *Note that the ACC function and unlock bypass modes are not available when the Secured Silicon Region is enabled.*

8.13.1 Factory Locked: Secured Silicon Region Programmed and Protected At the Factory

In a factory locked device, the Secured Silicon Region is protected when the device is shipped from the factory. The Secured Silicon Region cannot be modified in any way. The device is preprogrammed with both a random number and a secure ESN. The 8-word random number is at addresses 000000h–000007h in word mode (or 000000h–00000Fh in byte mode). The secure ESN is programmed in the next 8 words at addresses 000008h–00000Fh (or 000010h–00001Fh in byte mode). The device is available preprogrammed with one of the following:

■ A random, secure ESN only

■ Customer code through Cypress programming services

■ Both a random, secure ESN and customer code through Cypress programming services

Contact an your local sales office for details on using Cypress programming services.

8.13.2 Customer Lockable: Secured Silicon Region NOT Programmed or Protected At the Factory

If the security feature is not required, the Secured Silicon Region can be treated as an additional Flash memory space. The Secured Silicon Region can be read any number of times, but can be programmed and locked only once. Note that the accelerated programming (ACC) and unlock bypass functions are not available when programming the Secured Silicon Region.

■ Write the three-cycle Enter Secured Silicon Region command sequence, and then follow the in-system sector protect algorithm as shown in Figure 4 on page 21, except that *RESET# may be at either V_{IH} or V_{ID}.* This allows in-system protection of the Secured Silicon Region without raising any device pin to a high voltage. Note that this method is only applicable to the Secured Silicon Region.

■ To verify the protect/unprotect status of the Secured Silicon Region, follow the algorithm shown in Figure 5 on page 23.

Once the Secured Silicon Region is locked and verified, the system must write the Exit Secured Silicon Region command sequence to return to reading and writing the remainder of the array.

The Secured Silicon Region lock must be used with caution since, once locked, there is no procedure available for unlocking the Secured Silicon Region and none of the bits in the Secured Silicon Region memory space can be modified in any way.

Figure 5. Secured Silicon Region Protect Verify
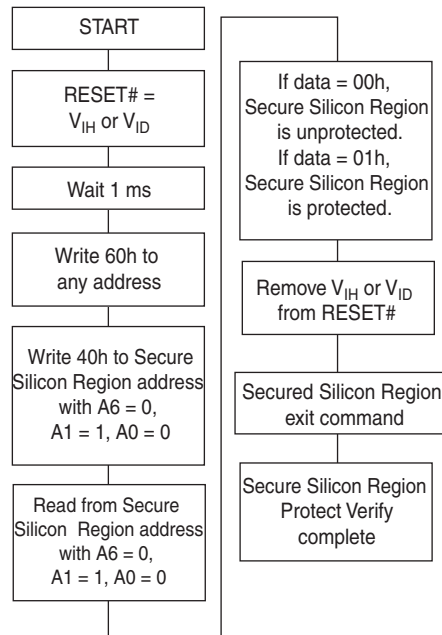

8.14 Hardware Data Protection

The command sequence requirement of unlock cycles for programming or erasing provides data protection against inadvertent writes (refer to Table 12 on page 32 for command definitions). In addition, the following hardware data protection measures prevent accidental erasure or programming, which might otherwise be caused by spurious system level signals during V_{CC} power-up and power-down transitions, or from system noise.

8.14.1 Low V_{CC} Write Inhibit

When V_{CC} is less than V_{LKO}, the device does not accept any write cycles. This protects data during V_{CC} power-up and power-down. The command register and all internal program/erase circuits are disabled, and the device resets to the read mode. Subsequent writes are ignored until V_{CC} is greater than V_{LKO}. The system must provide the proper signals to the control pins to prevent unintentional writes when V_{CC} is greater than V_{LKO}.

8.14.2 Write Pulse Glitch Protection

Noise pulses of less than 5 ns (typical) on OE#, CE# or WE# do not initiate a write cycle.

8.14.3 Logical Inhibit

Write cycles are inhibited by holding any one of OE# = V_{IL}, CE# = V_{IH} or WE# = V_{IH}. To initiate a write cycle, CE# and WE# must be a logical zero while OE# is a logical one.

8.14.4 Power-Up Write Inhibit

If WE# = CE# = V_{IL} and OE# = V_{IH} during power up, the device does not accept commands on the rising edge of WE#. The internal state machine is automatically reset to the read mode on power-up.

9. Common Flash Memory Interface (CFI)

The Common Flash Interface (CFI) specification outlines device and host system software interrogation handshake, which allows specific vendor-specified software algorithms to be used for entire families of devices. Software support can then be device-independent, JEDEC ID-independent, and forward- and backward-compatible for the specified flash device families. Flash vendors can standardize their existing interfaces for long-term compatibility.

This device enters the CFI Query mode when the system writes the CFI Query command, 98h, to address 55h in word mode (or address AAh in byte mode), any time the device is ready to read array data. The system can read CFI information at the addresses given in Table 8 on page 24 to Table 11 on page 25. To terminate reading CFI data, the system must write the reset command. The CFI Query mode is not accessible when the device is executing an Embedded Program or embedded Erase algorithm.

The system can also write the CFI query command when the device is in the autoselect mode via the command register only (high voltage method does not apply). The device enters the CFI query mode, and the system can read CFI data at the addresses given in Table 8 on page 24 to Table 11 on page 25. The system must write the reset command to return to reading array data.

For further information, please refer to the CFI Specification and CFI Publication 100. Contact your local sales office for copies of these documents.

Table 8. CFI Query Identification String

Addresses (Word Mode)	Addresses (Byte Mode)	Data	Description
10h 11h 12h	20h 22h 24h	0051h 0052h 0059h	Query Unique ASCII string "QRY"
13h 14h	26h 28h	0002h 0000h	Primary OEM Command Set

5Bh	B6h	0017h	Bank 4 Region Information X = Number of Sectors in Bank 4

10. Command Definitions

Writing specific address and data sequences into the command register initiates device operations. Table 12 on page 32 defines the valid register command sequences. *Writing incorrect address and data values or writing them in the improper sequence may place the device in an unknown state. A reset command is then required to return the device to reading array data.*

All addresses are latched on the falling edge of WE# or CE#, whichever happens later. All data is latched on the rising edge of WE# or CE#, whichever happens first. Refer to Section 17. AC Characteristics on page 45 for timing diagrams.

10.1 Reading Array Data

The device is automatically set to reading array data after device power-up. No commands are required to retrieve data. Each bank is ready to read array data after completing an Embedded Program or Embedded Erase algorithm.

After the device accepts an Erase Suspend command, the corresponding bank enters the erase-suspend-read mode, after which the system can read data from any non-erase-suspended sector within the same bank. The system can read array data using the standard read timing, except that if it reads at an address within erase-suspended sectors, the device outputs status data. After completing a programming operation in the Erase Suspend mode, the system may once again read array data with the same exception. See Section 10.8 Erase Suspend/Erase Resume Commands on page 31 for more information.

The system *must* issue the reset command to return a bank to the read (or erase-suspend-read) mode if DQ5 goes high during an active program or erase operation, or if the bank is in the autoselect mode. See Section 10.2 Reset Command on page 27 for more information.

See Section 8.2 Requirements for Reading Array Data on page 11 for more information. Section 17.1 Read-Only Operations on page 45 provides the read parameters, and Figure 16 on page 45 shows the timing diagram.

10.2 Reset Command

Writing the reset command resets the banks to the read or erase-suspend-read mode. Address bits are don't cares for this command.

The reset command may be written between the sequence cycles in an erase command sequence before erasing begins. This resets the bank to which the system was writing to the read mode. Once erasure begins, however, the device ignores reset commands until the operation is complete.

The reset command may be written between the sequence cycles in a program command sequence before programming begins. This resets the bank to which the system was writing to the read mode. If the program command sequence is written to a bank that is in the Erase Suspend mode, writing the reset command returns that bank to the erase-suspend-read mode. Once programming begins, however, the device ignores reset commands until the operation is complete.

The reset command may be written between the sequence cycles in an autoselect command sequence. Once in the autoselect mode, the reset command must be written to return to the read mode. If a bank entered the autoselect mode while in the Erase Suspend mode, writing the reset command returns that bank to the erase-suspend-read mode.

If DQ5 goes high during a program or erase operation, writing the reset command returns the bank to the read mode (or erase-suspend-read mode if that bank was in Erase Suspend). Please note that the RY/BY# signal remains low until this reset is issued.

10.3   Autoselect Command Sequence

The autoselect command sequence allows the host system to access the manufacturer and device codes, and determine whether or not a sector is protected. The autoselect command sequence may be written to an address within a bank that is either in the read or erase-suspend-read mode. The autoselect command may not be written while the device is actively programming or erasing in another bank.

The autoselect command sequence is initiated by first writing two unlock cycles. This is followed by a third write cycle that contains the bank address and the autoselect command. The bank then enters the autoselect mode. The system may read any number of autoselect codes without re-initiating the command sequence.

Table 12 on page 32 shows the address and data requirements. To determine sector protection information, the system must write to the appropriate bank address (BA) and sector address (SA). Table 4 on page 16 shows the address range and bank number associated with each sector.

The system must write the reset command to return to the read mode (or erase-suspend-read mode if the bank was previously in Erase Suspend).

10.4   Enter Secured Silicon Region/Exit Secured Silicon Region Command Sequence

The system can access the Secured Silicon Region by issuing the three-cycle Enter Secured Silicon Region command sequence. The device continues to access the Secured Silicon Region until the system issues the four-cycle Exit Secured Silicon Region command sequence. The Exit Secured Silicon Region command sequence returns the device to normal operation. The Secured Silicon Region is not accessible when the device is executing an Embedded Program or embedded Erase algorithm. Table 12 on page 32 shows the address and data requirements for both command sequences. See also Section 8.13 Secured Silicon Region on page 22 for further information. *Note that the ACC function and unlock bypass modes are not available when the Secured Silicon Region is enabled.*

10.5   Byte/Word Program Command Sequence

The system may program the device by word or byte, depending on the state of the BYTE# pin. Programming is a four-bus-cycle operation. The program command sequence is initiated by writing two unlock write cycles, followed by the program set-up command. The program address and data are written next, which in turn initiate the Embedded Program algorithm. The system is *not* required to provide further controls or timings. The device automatically provides internally generated program pulses and verifies the programmed cell margin. Table 12 on page 32 shows the address and data requirements for the byte program command sequence.

When the Embedded Program algorithm is complete, that bank then returns to the read mode and addresses are no longer latched. The system can determine the status of the program operation by using DQ7, DQ6, or RY/BY#. Refer to Section 11. Write Operation Status on page 34 for information on these status bits.

Any commands written to the device during the Embedded Program Algorithm are ignored. Note that a **hardware reset** immediately terminates the program operation. The program command sequence should be reinitiated once that bank has returned to the read mode, to ensure data integrity. *Note that the Secured Silicon Region, autoselect, and CFI functions are unavailable when a program operation is in progress.*

Programming is allowed in any sequence and across sector boundaries. **A bit cannot be programmed from *0* back to a *1*.** Attempting to do so may cause that bank to set DQ5 = 1, or cause the DQ7 and DQ6 status bits to indicate the operation was successful. However, a succeeding read will show that the data is still 0. Only erase operations can convert a 0 to a *1*.

10.5.1 Unlock Bypass Command Sequence

The unlock bypass feature allows the system to program bytes or words to a bank faster than using the standard program command sequence. The unlock bypass command sequence is initiated by first writing two unlock cycles. This is followed by a third write cycle containing the unlock bypass command, 20h. That bank then enters the unlock bypass mode. A two-cycle unlock bypass program command sequence is all that is required to program in this mode. The first cycle in this sequence contains the unlock bypass program command, A0h; the second cycle contains the program address and data. Additional data is programmed in the same manner. This mode dispenses with the initial two unlock cycles required in the standard program command sequence, resulting in faster total programming time. Table 12 on page 32 shows the requirements for the command sequence.

During the unlock bypass mode, only the Unlock Bypass Program and Unlock Bypass Reset commands are valid. To exit the unlock bypass mode, the system must issue the two-cycle unlock bypass reset command sequence. (See Table 12 on page 32).

The device offers accelerated program operations through the WP#/ACC pin. When the system asserts V_{HH} on the WP#/ACC pin, the device automatically enters the Unlock Bypass mode. The system may then write the two-cycle Unlock Bypass program command sequence. The device uses the higher voltage on the WP#/ACC pin to accelerate the operation. Note that the WP#/ACC pin must not be at V_{HH} for any operation other than accelerated programming, or device damage may result. In addition, the WP#/ACC pin must not be left floating or unconnected; inconsistent behavior of the device may result.

Figure 6 on page 29 illustrates the algorithm for the program operation. Refer to Section 17.4 Erase and Program Operations on page 48 for parameters, and Figure 20 on page 49 for timing diagrams.

Figure 6. Program Operation[8]
10.6   Chip Erase Command Sequence

Chip erase is a six bus cycle operation. The chip erase command sequence is initiated by writing two unlock cycles, followed by a set-up command. Two additional unlock write cycles are then followed by the chip erase command, which in turn invokes the Embedded Erase algorithm. The device does *not* require the system to preprogram prior to erase. The Embedded Erase algorithm automatically preprograms and verifies the entire memory for an all zero data pattern prior to electrical erase. The system is not required to provide any controls or timings during these operations. Table 12 on page 32 shows the address and data requirements for the chip erase command sequence.

When the Embedded Erase algorithm is complete, that bank returns to the read mode and addresses are no longer latched. The system can determine the status of the erase operation by using DQ7, DQ6, DQ2, or RY/BY#. Refer to Section 11. Write Operation Status on page 34 for information on these status bits.

Any commands written during the chip erase operation are ignored. However, note that a **hardware reset** immediately terminates the erase operation. If that occurs, the chip erase command sequence should be reinitiated once that bank has returned to reading array data, to ensure data integrity. *Note that the Secured Silicon Region, autoselect, and CFI functions are unavailable when an erase operation is in progress.*

Figure 7 on page 31 illustrates the algorithm for the erase operation. Refer to Section 17.4 Erase and Program Operations on page 48 for parameters, and Figure 22 on page 50 for timing diagrams.

10.7   Sector Erase Command Sequence

Sector erase is a six bus cycle operation. The sector erase command sequence is initiated by writing two unlock cycles, followed by a set-up command. Two additional unlock cycles are written, and are then followed by the address of the sector to be erased, and the sector erase command. Table 12 on page 32 shows the address and data requirements for the sector erase command sequence.

The device does *not* require the system to preprogram prior to erase. The Embedded Erase algorithm automatically programs and verifies the entire sector for an all zero data pattern prior to electrical erase. The system is not required to provide any controls or timings during these operations.

After the command sequence is written, a sector erase time-out of 50 µs occurs. During the time-out period, additional sector addresses and sector erase commands may be written. However, these additional erase commands are only one bus cycle long and should be identical to the sixth cycle of the standard erase command explained above. Loading the sector erase buffer may be done in any sequence, and the number of sectors may be from one sector to all sectors. The time between these additional cycles must be less than 50 µs, otherwise erasure may begin. Any sector erase address and command following the exceeded time-out may or may not be accepted. It is recommended that processor interrupts be disabled during this time to ensure all commands are accepted. The interrupts can be re-enabled after the last Sector Erase command is written. **If any command other than 30h, B0h, F0h is input during the time-out period, the normal operation will not be guaranteed.** The system must rewrite the command sequence and any additional addresses and commands.

The system can monitor DQ3 to determine if the sector erase timer has timed out (See the section on DQ3: Sector Erase Timer.). The time-out begins from the rising edge of the final WE# or CE# pulse (first rising edge) in the command sequence.

When the Embedded Erase algorithm is complete, the bank returns to reading array data and addresses are no longer latched. Note that while the Embedded Erase operation is in progress, the system can read data from the non-erasing bank. The system can determine the status of the erase operation by reading DQ7, DQ6, DQ2, or RY/BY# in the erasing bank. Refer to Section 11. Write Operation Status on page 34 for information on these status bits.

Once the sector erase operation has begun, only the Erase Suspend command is valid. All other commands are ignored. However, note that a **hardware reset** immediately terminates the erase operation. If that occurs, the sector erase command sequence should be reinitiated once that bank has returned to reading array data, to ensure data integrity. *Note that the Secured Silicon Region, autoselect, and CFI functions are unavailable when an erase operation is in progress.*

Figure 7 on page 31 illustrates the algorithm for the erase operation. Refer to Section 17.4 Erase and Program Operations on page 48 for parameters, and Figure 22 on page 50 for timing diagrams.

Figure 7. Erase Operation[9, 10]
10.8 Erase Suspend/Erase Resume Commands

The Erase Suspend command, B0h, allows the system to interrupt a sector erase operation and then read data from, or program data to, any sector not selected for erasure. The bank address is required when writing this command. This command is valid only during the sector erase operation, including the 50 µs time-out period during the sector erase command sequence. The Erase Suspend command is ignored if written during the chip erase operation or Embedded Program algorithm. The bank address must contain one of the sectors currently selected for erase.

When the Erase Suspend command is written during the sector erase operation, the device requires a maximum of 35 µs to suspend the erase operation. However, when the Erase Suspend command is written during the sector erase time-out, the device immediately terminates the time-out period and suspends the erase operation.

After the erase operation has been suspended, the bank enters the erase-suspend-read mode. The system can read data from or program data to any sector not selected for erasure. (The device *erase suspends* all sectors selected for erasure.) It is not recommended to program the Secured Silicon Region after an erase suspend, as proper device functionality cannot be guaranteed. Reading at any address within erase-suspended sectors produces status information on DQ7–DQ0. The system can use DQ7, or DQ6 and DQ2 together, to determine if a sector is actively erasing or is erase-suspended. Refer to Section 11. Write Operation Status on page 34 for information on these status bits.

After an erase-suspended program operation is complete, the bank returns to the erase-suspend-read mode. The system can determine the status of the program operation using the DQ7 or DQ6 status bits, just as in the standard Byte Program operation. Refer to Section 11. Write Operation Status on page 34 for more information.

In the erase-suspend-read mode, the system can also issue the autoselect command sequence. The device allows reading autoselect codes even at addresses within erasing sectors, since the codes are not stored in the memory array. When the device exits the autoselect mode, the device reverts to the Erase Suspend mode, and is ready for another valid operation. Refer to Section 8.9 Autoselect Mode on page 17 and Section 10.3 Autoselect Command Sequence on page 28 for details.

To resume the sector erase operation, the system must write the Erase Resume command. The bank address of the erase-suspended bank is required when writing this command. Further writes of the Resume command are ignored. Another Erase Suspend command can be written after the chip has resumed erasing.

Notes
9. See Table 12 on page 32 for erase command sequence.
10. See the section on DQ3 for information on the sector erase timer.

Table 12. S29JL064J Command Definitions

Command Sequence[11]		Cycles	Bus Cycles[Notes 12 through 15]										
			First		Second		Third		Fourth		Fifth		Sixth

Legend

X = Don't care

RA = Address of the memory location to be read.

RD = Data read from location RA during read operation.

PA = Address of the memory location to be programmed. Addresses latch on the falling edge of the WE# or CE# pulse, whichever happens later.

PD = Data to be programmed at location PA. Data latches on the rising edge of WE# or CE# pulse, whichever happens first.

SA = Address of the sector to be verified (in autoselect mode) or erased. Address bits A21–A12 uniquely select any sector. Refer to Table 4 on page 16 for information on sector addresses.

BA = Address of the bank that is being switched to autoselect mode, is in bypass mode, or is being erased. A21–A19 uniquely select a bank.

Notes

11. See Table 2 on page 10 for description of bus operations.
12. All values are in hexadecimal.
13. Except for the read cycle and the fourth, fifth, and sixth cycle of the autoselect command sequence, all bus cycles are write cycles.
14. Data bits DQ15–DQ8 are don't care in command sequences, except for RD and PD.
15. Unless otherwise noted, address bits A21–A11 are don't cares for unlock and command cycles, unless SA or PA is required.
16. No unlock or command cycles required when bank is reading array data.
17. The Reset command is required to return to the read mode (or to the erase-suspend-read mode if previously in Erase Suspend) when a bank is in the autoselect mode, or if DQ5 goes high (while the bank is providing status information).
18. The fourth cycle of the autoselect command sequence is a read cycle. The system must provide the bank address to obtain the manufacturer ID, device ID, or Secured Silicon Region factory protect information. Data bits DQ15–DQ8 are don't care. While reading the autoselect addresses, the bank address must be the same until a reset command is given. See Section 10.3 Autoselect Command Sequence on page 28 for more information.
19. The device ID must be read across the fourth, fifth, and sixth cycles.
20. The data is 81h for factory locked, 41h for customer locked, and 01h for not factory/customer locked.
21. The data is 00h for an unprotected sector/sector block and 01h for a protected sector/sector block.
22. The Unlock Bypass command is required prior to the Unlock Bypass Program command.
23. The Unlock Bypass Reset command is required to return to the read mode when the bank is in the unlock bypass mode.
24. The system may read and program in non-erasing sectors, or enter the autoselect mode, when in the Erase Suspend mode. The Erase Suspend command is valid only during a sector erase operation, and requires the bank address.
25. The Erase Resume command is valid only during the Erase Suspend mode, and requires the bank address.
26. Command is valid when device is ready to read array data or when device is in autoselect mode.
27. Additional sector erase commands during the time-out period after an initial sector erase are one cycle long and identical to the sixth cycle of the sector erase command sequence (SA / 30).

11. Write Operation Status

The device provides several bits to determine the status of a program or erase operation: DQ2, DQ3, DQ5, DQ6, and DQ7. Table 13 on page 38 and the following subsections describe the function of these bits. DQ7 and DQ6 each offer a method for determining whether a program or erase operation is complete or in progress. The device also provides a hardware-based output signal, RY/BY#, to determine whether an Embedded Program or Erase operation is in progress or has been completed.

11.1 DQ7: Data# Polling

The Data# Polling bit, DQ7, indicates to the host system whether an Embedded Program or Erase algorithm is in progress or completed, or whether a bank is in Erase Suspend. Data# Polling is valid after the rising edge of the final WE# pulse in the command sequence.

During the Embedded Program algorithm, the device outputs on DQ7 the complement of the datum programmed to DQ7. This DQ7 status also applies to programming during Erase Suspend. When the Embedded Program algorithm is complete, the device outputs the datum programmed to DQ7. The system must provide the program address to read valid status information on DQ7. If a program address falls within a protected sector, Data# Polling on DQ7 is active for approximately 1 μs, then that bank returns to the read mode.

During the Embedded Erase algorithm, Data# Polling produces a *0* on DQ7. When the Embedded Erase algorithm is complete, or if the bank enters the Erase Suspend mode, Data# Polling produces a *1* on DQ7. The system must provide an address within any of the sectors selected for erasure to read valid status information on DQ7.

After an erase command sequence is written, if all sectors selected for erasing are protected, Data# Polling on DQ7 is active for approximately 3 ms, then the bank returns to the read mode. If not all selected sectors are protected, the Embedded Erase algorithm erases the unprotected sectors, and ignores the selected sectors that are protected. However, if the system reads DQ7 at an address within a protected sector, the status may not be valid.

When the system detects DQ7 has changed from the complement to true data, it can read valid data at DQ15–DQ0 (or DQ7–DQ0 for x8-only device) on the *following* read cycles. Just prior to the completion of an Embedded Program or Erase operation, DQ7 may change asynchronously with DQ15–DQ8 (DQ7–DQ0 for x8-only device) while Output Enable (OE#) is asserted low. That is, the device may change from providing status information to valid data on DQ7. Depending on when the system samples the DQ7 output, it may read the status or valid data. Even if the device has completed the program or erase operation and DQ7 has valid data, the data outputs on DQ15–DQ0 may be still invalid. Valid data on DQ15–DQ0 (or DQ7–DQ0 for x8-only device) will appear on successive read cycles.

Table 13 on page 38 shows the outputs for Data# Polling on DQ7. Figure 8 on page 35 shows the Data# Polling algorithm. Figure 24 on page 51 shows the Data# Polling timing diagram.

Figure 8. Data# Polling Algorithm[28, 29]
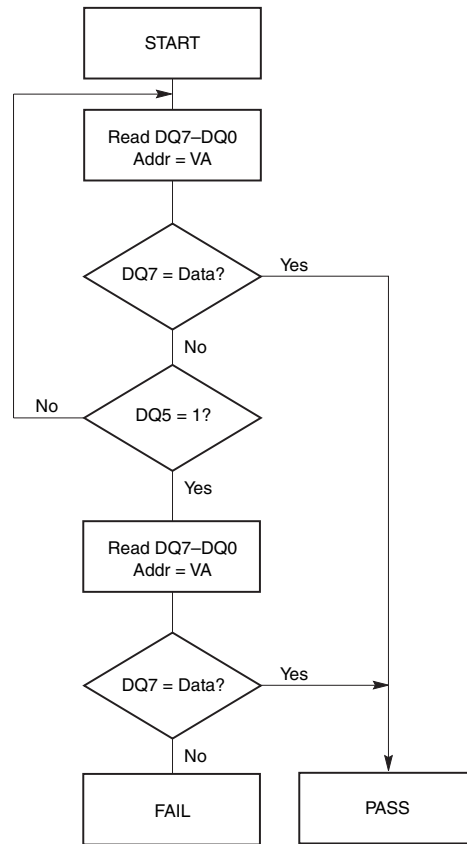

11.2   RY/BY#: Ready/Busy#

The RY/BY# is a dedicated, open-drain output pin which indicates whether an Embedded Algorithm is in progress or complete. The RY/BY# status is valid after the rising edge of the final WE# pulse in the command sequence. Since RY/BY# is an open-drain output, several RY/BY# pins can be tied together in parallel with a pull-up resistor to V_{CC}.

If the output is low (Busy), the device is actively erasing or programming. (This includes programming in the Erase Suspend mode.) If the output is high (Ready), the device is in the read mode, the standby mode, or one of the banks is in the erase-suspend-read mode.

Table 13 on page 38 shows the outputs for RY/BY#. When DQ5 is set to "1", RY/BY# will be in the BUSY state, or "0".

Notes
28. VA = Valid address for programming. During a sector erase operation, a valid address is any sector address within the sector being erased. During chip erase, a valid address is any non-protected sector address.
29. DQ7 should be rechecked even if DQ5 = 1 because DQ7 may change simultaneously with DQ5.

11.3 DQ6: Toggle Bit I

Toggle Bit I on DQ6 indicates whether an Embedded Program or Erase algorithm is in progress or complete, or whether the device has entered the Erase Suspend mode. Toggle Bit I may be read at any address, and is valid after the rising edge of the final WE# pulse in the command sequence (prior to the program or erase operation), and during the sector erase time-out.

During an Embedded Program or Erase algorithm operation, successive read cycles to any address cause DQ6 to toggle. The system may use either OE# or CE# to control the read cycles. When the operation is complete, DQ6 stops toggling.

After an erase command sequence is written, if all sectors selected for erasing are protected, DQ6 toggles for approximately 3 ms, then returns to reading array data. If not all selected sectors are protected, the Embedded Erase algorithm erases the unprotected sectors, and ignores the selected sectors that are protected.

The system can use DQ6 and DQ2 together to determine whether a sector is actively erasing or is erase-suspended. When the device is actively erasing (that is, the Embedded Erase algorithm is in progress), DQ6 toggles. When the device enters the Erase Suspend mode, DQ6 stops toggling. However, the system must also use DQ2 to determine which sectors are erasing or erase-suspended. Alternatively, the system can use DQ7 (see Section 11.1 DQ7: Data# Polling on page 34).

If a program address falls within a protected sector, DQ6 toggles for approximately 1 µs after the program command sequence is written, then returns to reading array data.

DQ6 also toggles during the erase-suspend-program mode, and stops toggling once the Embedded Program algorithm is complete.

Figure 9. Toggle Bit Algorithm[30]
Note
30. The system should recheck the toggle bit even if DQ5 = 1 because the toggle bit may stop toggling as DQ5 changes to 1. See the subsections on DQ6 and DQ2 for more information.

11.4 DQ2: Toggle Bit II

The *Toggle Bit II* on DQ2, when used with DQ6, indicates whether a particular sector is actively erasing (that is, the Embedded Erase algorithm is in progress), or whether that sector is erase-suspended. Toggle Bit II is valid after the rising edge of the final WE# pulse in the command sequence.

DQ2 toggles when the system reads at addresses within those sectors that have been selected for erasure. (The system may use either OE# or CE# to control the read cycles.) But DQ2 cannot distinguish whether the sector is actively erasing or is erase-suspended. DQ6, by comparison, indicates whether the device is actively erasing, or is in Erase Suspend, but cannot distinguish which sectors are selected for erasure. Thus, both status bits are required for sector and mode information. Refer to Table 13 on page 38 to compare outputs for DQ2 and DQ6.

Figure 9 on page 36 shows the toggle bit algorithm in flowchart form, and Section 11.4 DQ2: Toggle Bit II on page 37 explains the algorithm. See also Section 11.3 DQ6: Toggle Bit I on page 36. Figure 25 on page 51 shows the toggle bit timing diagram. Figure 26 on page 52 shows the differences between DQ2 and DQ6 in graphical form.

11.5 Reading Toggle Bits DQ6/DQ2

Refer to Figure 9 on page 36 for the following discussion. Whenever the system initially begins reading toggle bit status, it must read DQ15–DQ0 (or DQ7–DQ0 for x8-only device) at least twice in a row to determine whether a toggle bit is toggling. Typically, the system would note and store the value of the toggle bit after the first read. After the second read, the system would compare the new value of the toggle bit with the first. If the toggle bit is not toggling, the device has completed the program or erase operation. The system can read array data on DQ15–DQ0 (or DQ7–DQ0 for x8-only device) on the following read cycle.

However, if after the initial two read cycles, the system determines that the toggle bit is still toggling, the system also should note whether the value of DQ5 is high (see the section on DQ5). If it is, the system should then determine again whether the toggle bit is toggling, since the toggle bit may have stopped toggling just as DQ5 went high. If the toggle bit is no longer toggling, the device has successfully completed the program or erase operation. If it is still toggling, the device did not completed the operation successfully, and the system must write the reset command to return to reading array data.

The remaining scenario is that the system initially determines that the toggle bit is toggling and DQ5 has not gone high. The system may continue to monitor the toggle bit and DQ5 through successive read cycles, determining the status as described in the previous paragraph. Alternatively, it may choose to perform other system tasks. In this case, the system must start at the beginning of the algorithm when it returns to determine the status of the operation (top of Figure 9 on page 36).

11.6 DQ5: Exceeded Timing Limits

DQ5 indicates whether the program or erase time has exceeded a specified internal pulse count limit. Under these conditions DQ5 produces a *1*, indicating that the program or erase cycle was not successfully completed.

The device may output a *1* on DQ5 if the system tries to program a *1* to a location that was previously programmed to *0*. **Only an erase operation can change a *0* back to a *1*.** Under this condition, the device halts the operation, and when the timing limit has been exceeded, DQ5 produces a *1*.

Under both these conditions, the system must write the reset command to return to the read mode (or to the erase-suspend-read mode if a bank was previously in the erase-suspend-program mode).

11.7   DQ3: Sector Erase Timer

After writing a sector erase command sequence, the system may read DQ3 to determine whether or not erasure has begun. (The sector erase timer does not apply to the chip erase command.) If additional sectors are selected for erasure, the entire time-out also applies after each additional sector erase command. When the time-out period is complete, DQ3 switches from a *0* to a *1*. If the time between additional sector erase commands from the system can be assumed to be less than 50 µs, the system need not monitor DQ3. See also Section 10.7 Sector Erase Command Sequence on page 30.

After the sector erase command is written, the system should read the status of DQ7 (Data# Polling) or DQ6 (Toggle Bit I) to ensure that the device has accepted the command sequence, and then read DQ3. If DQ3 is *1*, the Embedded Erase algorithm has begun; all further commands (except Erase Suspend) are ignored until the erase operation is complete. If DQ3 is *0*, the device will accept additional sector erase commands. To ensure the command has been accepted, the system software should check the status of DQ3 prior to and following each subsequent sector erase command. If DQ3 is high on the second status check, the last command might not have been accepted. The RDY/BSY# pin will be in the BUSY state under this condition.

Table 13 on page 38 shows the status of DQ3 relative to the other status bits.

Table 13. Write Operation Status

Status			DQ7[32]	DQ6	DQ5[31]	DQ3	DQ2[32]	RY/BY#
Standard Mode	Embedded Program Algorithm		DQ7#	Toggle	0	N/A	No toggle	0
	Embedded Erase Algorithm	in busy erasing sector	0	Toggle	0	1	Toggle	0
		in not busy erasing sector	0	Toggle	0	1	No toggle	0
Erase Suspend Mode	Erase-Suspend-Read	Erase Suspended Sector	1	No toggle	0	N/A	Toggle	1
		Non-Erase Suspended Sector	Data	Data	Data	Data	Data	1
	Erase-Suspend-Program		DQ7#	Toggle	0	N/A	N/A	0

Notes
31. DQ5 switches to 1 when an Embedded Program or Embedded Erase operation has exceeded the maximum timing limits. Refer to the section on DQ5 for more information.
32. DQ7 and DQ2 require a valid address when reading status information. Refer to the appropriate subsection for further details.
33. When reading write operation status bits, the system must always provide the bank address where the Embedded Algorithm is in progress. The device outputs array data if the system addresses a non-busy bank.

12. Absolute Maximum Ratings

Storage Temperature, Plastic Packages	–65°C to +150°C
Ambient Temperature with Power Applied	–65°C to +125°C
Voltage with Respect to Ground	
V_{CC}[34]	–0.5V to +4.0V
A9 and RESET#[35]	–0.5V to +12.5V
WP#/ACC	–0.5V to +9.5V
All other pins[34]	–0.5V to V_{CC} +0.5V
Output Short Circuit Current[36]	200 mA

Notes

34. Minimum DC voltage on input or I/O pins is –0.5V. During voltage transitions, input or I/O pins may overshoot V_{SS} to –2.0V for periods of up to 20 ns. Maximum DC voltage on input or I/O pins is V_{CC} +0.5V. See Figure 10 on page 39. During voltage transitions, input or I/O pins may overshoot to V_{CC} +2.0V for periods up to 20 ns. See Figure 11 on page 39.

35. Minimum DC input voltage on pins A9, OE#, RESET#, and WP#/ACC is –0.5V. During voltage transitions, A9, OE#, WP#/ACC, and RESET# may overshoot V_{SS} to –2.0V for periods of up to 20 ns. See Figure 10 on page 39. Maximum DC input voltage on pin A9 is +12.5V which may overshoot to +14.0V for periods up to 20 ns. Maximum DC input voltage on WP#/ACC is +9.5V which may overshoot to +12.0V for periods up to 20 ns.

36. No more than one output may be shorted to ground at a time. Duration of the short circuit should not be greater than one second.

37. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational sections of this data sheet is not implied. Exposure of the device to absolute maximum rating conditions for extended periods may affect device reliability.

Figure 10. Maximum Negative Overshoot Waveform
Figure 11. Maximum Positive Overshoot Waveform
13. Operating Ranges

Industrial (I) Devices
Ambient Temperature (T_A) −40°C to +85°C

Automotive (A) Devices
Ambient Temperature (T_A) −40°C to +85°C

V_{CC} Supply Voltages
V_{CC} for standard voltage range 2.7V to 3.6V

Operating ranges define those limits between which the functionality of the device is guaranteed.

14. DC Characteristics

14.1 CMOS Compatible

Parameter Symbol	Parameter Description	Test Conditions		Min	Typ	Max	Unit
I_{LI}	Input Load Current	$V_{IN} = V_{SS}$ to V_{CC}, $V_{CC} = V_{CC\ max}$				±1.0	µA
I_{LIT}	A9 and RESET# Input Load Current	$V_{CC} = V_{CC\ max}$, OE# = V_{IH}; A9 or RESET# = 12.5V				35	µA
I_{LO}	Output Leakage Current	$V_{OUT} = V_{SS}$ to V_{CC}, $V_{CC} = V_{CC\ max}$, OE# = V_{IH}				±1.0	µA
I_{LR}	Reset Leakage Current	$V_{CC} = V_{CC\ max}$; RESET# = 12.5V				35	µA
I_{CC1}	V_{CC} Active Read Current[38, 39]	CE# = V_{IL}, OE# = V_{IH}, Byte Mode	5 MHz		10	16	mA
			1 MHz		2	4	
		CE# = V_{IL}, OE# = V_{IH}, Word Mode	5 MHz		10	16	
			1 MHz		2	4	
I_{CC2}	V_{CC} Active Write Current[38, 39]	CE# = V_{IL}, OE# = V_{IH}, WE# = V_{IL}			15	30	mA
I_{CC3}	V_{CC} Standby Current (Note 39)	CE#, RESET# = $V_{CC} \pm 0.3V$			0.2	5	µA
I_{CC4}	V_{CC} Reset Current (Note 39)	RESET# = $V_{SS} \pm 0.3V$			0.2	5	µA
I_{CC5}	Automatic Sleep Mode[39, 41]	$V_{IH} = V_{CC} \pm 0.3V$; $V_{IL} = V_{SS} \pm 0.3V$			0.2	5	µA
I_{CC6}	V_{CC} Active Read-While-Program Current[41]	CE# = V_{IL}, OE# = V_{IH}, 1 MHz	Byte		21	45	mA
			Word		21	45	
I_{CC7}	V_{CC} Active Read-While-Erase Current[41]	CE# = V_{IL}, OE# = V_{IH}, 1 MHz	Byte		21	45	mA
			Word		21	45	
I_{CC8}	V_{CC} Active Program-While-Erase-Suspended Current (Notes 39, 42)	CE# = V_{IL}, OE# = V_{IH}			17	35	mA
V_{IL}	Input Low Voltage			−0.5		0.8	V
V_{IH}	Input High Voltage			$0.7 \times V_{CC}$		$V_{CC} + 0.3$	V
V_{HH}	Voltage for WP#/ACC Sector Protect/Unprotect and Program Acceleration	$V_{CC} = 3.0V \pm 10\%$		8.5		9.5	V
V_{ID}	Voltage for Autoselect and Temporary Sector Unprotect	$V_{CC} = 3.0V \pm 10\%$		8.5		12.5	V
V_{OL}	Output Low Voltage	$I_{OL} = 2.0$ mA, $V_{CC} = V_{CC\ min}$				0.45	V
V_{OH1}	Output High Voltage	$I_{OH} = -2.0$ mA, $V_{CC} = V_{CC\ min}$		$0.85\ V_{CC}$			V
V_{OH2}		$I_{OH} = -100$ µA, $V_{CC} = V_{CC\ min}$		$V_{CC}-0.4$			
V_{LKO}	Low V_{CC} Lock-Out Voltage[42]			1.8	2.0	2.5	V

Notes
38. The I_{CC} current listed is typically less than 2 mA/MHz, with OE# at V_{IH}.
39. Maximum I_{CC} specifications are tested with $V_{CC} = V_{CC}$max.
40. I_{CC} active while Embedded Erase or Embedded Program is in progress.
41. Automatic sleep mode enables the low power mode when addresses remain stable for t_{ACC} + 30 ns. Typical sleep mode current is 200 nA.
42. Not 100% tested.

14.2 Zero-Power Flash

Figure 12. I_{CC1} Current vs. Time (Showing Active and Automatic Sleep Currents)[43]
Figure 13. Typical I_{CC1} vs. Frequency[44]
Notes
43. Addresses are switching at 1 MHz.
44. T = 25°C.

15. Test Conditions

Figure 14. Test Setup
Table 14. Test Specifications

Test Condition	55, 60	70	Unit
Output Load Capacitance, C_L	30	100	pF
Input Rise and Fall Times[45]	5		ns
Input Pulse Levels	0.0 or V_{CC}		V
Input timing measurement reference levels	0.5 V_{CC}		V
Output timing measurement reference levels	0.5 V_{CC}		V

Note
45. *Input rise and fall times are 0-100%.*

16. Key To Switching Waveforms
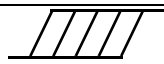

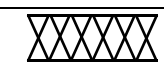

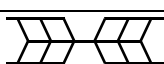

Waveform	Inputs	Outputs
	Steady	
	Changing from H to L	
	Changing from L to H	
	Don't Care, Any Change Permitted	Changing, State Unknown
	Does Not Apply	Center Line is High Impedance State (High-Z)

Figure 19. BYTE# Timings for Write Operations
Note
50. Refer to the Erase/Program Operations table for t_{AS} and t_{AH} specifications.

17.4 Erase and Program Operations

Parameter		Description			Speed Options			Unit
JEDEC	Std				55	60	70	
t_{AVAV}	t_{WC}	Write Cycle Time[51]		Min	55	60	70	ns
t_{AVWL}	t_{AS}	Address Setup Time		Min	0			ns
	t_{ASO}	Address Setup Time to OE# low during toggle bit polling		Min	15			ns
t_{WLAX}	t_{AH}	Address Hold Time		Min	30	35	40	ns
	t_{AHT}	Address Hold Time From CE# or OE# high during toggle bit polling		Min	0			ns
t_{DVWH}	t_{DS}	Data Setup Time		Min	30	35	40	ns
t_{WHDX}	t_{DH}	Data Hold Time		Min	0			ns
	t_{OEPH}	Output Enable High during toggle bit polling		Min	20			ns
t_{GHWL}	t_{GHWL}	Read Recovery Time Before Write (OE# High to WE# Low)		Min	0			ns
t_{ELWL}	t_{CS}	CE# Setup Time		Min	0			ns
t_{WHEH}	t_{CH}	CE# Hold Time		Min	0			ns
t_{WLWH}	t_{WP}	Write Pulse Width		Min	25	25	30	ns
t_{WHDL}	t_{WPH}	Write Pulse Width High		Min	25	25	30	ns
	$t_{SR/W}$	Latency Between Read and Write Operations		Min	0			ns
t_{WHWH1}	t_{WHWH1}	Programming Operation[52]	Byte	Typ	6			μs
			Word	Typ	6			
t_{WHWH1}	t_{WHWH1}	Accelerated Programming Operation, Word or Byte[52]		Typ	4			μs
t_{WHWH2}	t_{WHWH2}	Sector Erase Operation[52]		Typ	0.5			sec
	t_{VCS}	V$_{CC}$ Setup Time[51]		Min	50			μs
	t_{RB}	Write Recovery Time from RY/BY#		Min	0			ns
	t_{BUSY}	Program/Erase Valid to RY/BY# Delay		Max	90			ns
	t_{ESL}	Erase Suspend Latency		Max	35			μs

Notes
51. Not 100% tested.
52. See Section 18. Erase and Programming Performance on page 56 for more information.

Figure 20. Program Operation Timings[53, 54]
Figure 21. Accelerated Program Timing Diagram
Notes
53. PA = program address, PD = program data, D_{OUT} is the true data at the program address.
54. Illustration shows device in word mode.

Figure 22. Chip/Sector Erase Operation Timings[55, 56]
Figure 23. Back-to-back Read/Write Cycle Timings
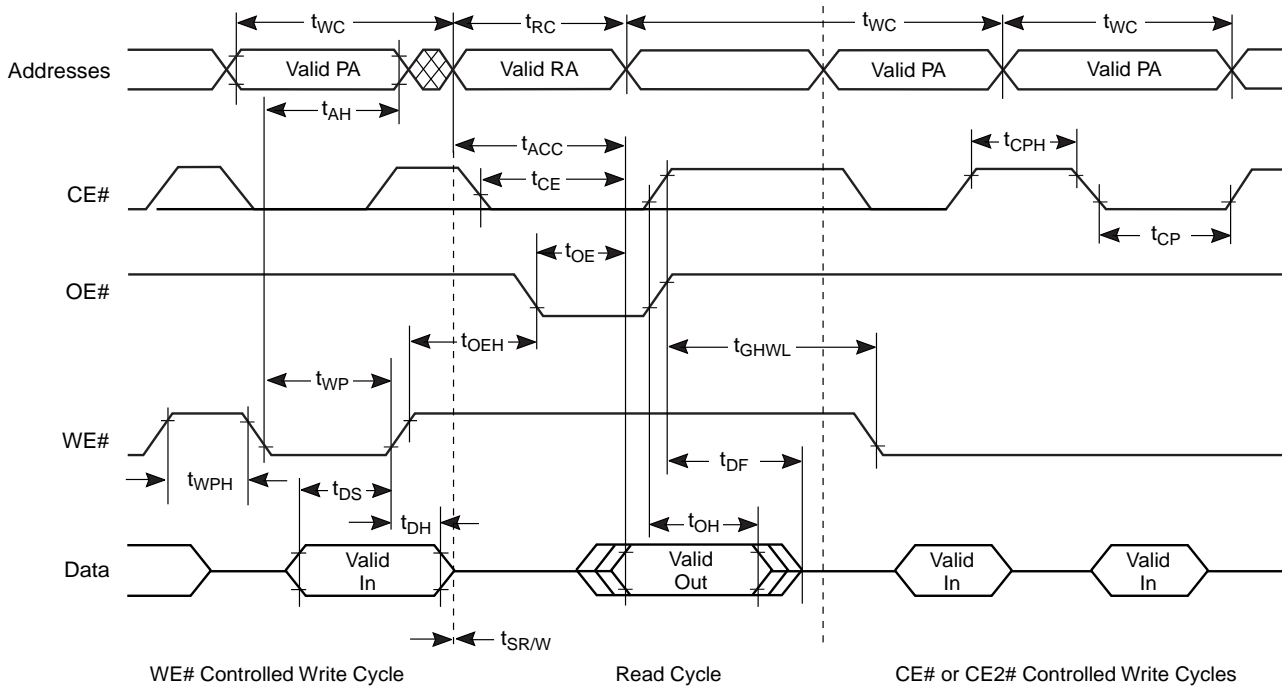

Notes
55. SA = sector address (for Sector Erase), VA = Valid Address for reading status data (see Section 11. Write Operation Status on page 34).
56. These waveforms are for the word mode.

Figure 24. Data# Polling Timings (During Embedded Algorithms)[57]
Figure 25. Toggle Bit Timings (During Embedded Algorithms)[58]
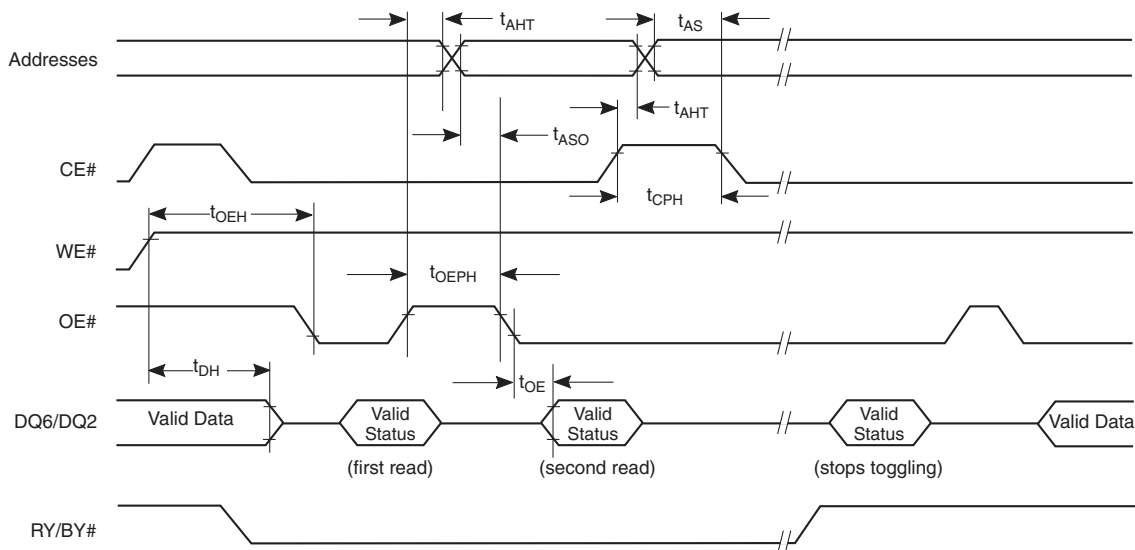

Notes
57. VA = Valid address. Illustration shows first status cycle after command sequence, last status read cycle, and array data read cycle.
58. VA = Valid address; not required for DQ6. Illustration shows first two status cycle after command sequence, last status read cycle, and array data read cycle.

Figure 26. DQ2 vs. DQ6[59]
17.5   Temporary Sector Unprotect

Parameter		Description		All Speed Options		Unit
JEDEC	Std					
	t_{VIDR}	V_{ID} Rise and Fall Time[60]	Min	500		ns
	t_{VHH}	V_{HH} Rise and Fall Time[60]	Min	250		ns
	t_{RSP}	RESET# Setup Time for Temporary Sector Unprotect	Min	4		µs
	t_{RRB}	RESET# Hold Time from RY/BY# High for Temporary Sector Unprotect	Min	4		µs
Note 60. Not 100% tested.						

Figure 27. Temporary Sector Unprotect Timing Diagram
Note
59. DQ2 toggles only when read at an address within an erase-suspended sector. The system may use OE# or CE# to toggle DQ2 and DQ6.

Figure 28. Sector/Sector Block Protect and Unprotect Timing Diagram[61]
17.6 Alternate CE# Controlled Erase and Program Operations

Parameter		Description			Speed Options			
JEDEC	Std.				55	60	70	Unit
t_{AVAV}	t_{WC}	Write Cycle Time[62]		Min	55	60	70	ns
t_{AVWL}	t_{AS}	Address Setup Time		Min	0			ns
t_{ELAX}	t_{AH}	Address Hold Time		Min	30	35	40	ns
t_{DVEH}	t_{DS}	Data Setup Time		Min	30	35	40	ns
t_{EHDX}	t_{DH}	Data Hold Time		Min	0			ns
t_{GHEL}	t_{GHEL}	Read Recovery Time Before Write (OE# High to WE# Low)		Min	0			ns
t_{WLEL}	t_{WS}	WE# Setup Time		Min	0			ns
t_{EHWH}	t_{WH}	WE# Hold Time		Min	0			ns
t_{ELEH}	t_{CP}	CE# Pulse Width		Min	25	25	40	ns
t_{EHEL}	t_{CPH}	CE# Pulse Width High		Min	25	25	30	ns
t_{WHWH1}	t_{WHWH1}	Programming Operation[63]	Byte	Typ	6			µs
			Word	Typ	6			
t_{WHWH1}	t_{WHWH1}	Accelerated Programming Operation, Word or Byte[63]		Typ	4			µs
t_{WHWH2}	t_{WHWH2}	Sector Erase Operation[63]		Typ	0.5			sec

Notes
62. Not 100% tested.
63. See Section 18. Erase and Programming Performance on page 56 for more information.

Figure 29. Alternate CE# Controlled Write (Erase/Program) Operation Timings[64, 65, 66, 67]

18. Erase and Programming Performance

Parameter	Typ[68]	Max[69]	Unit	Comments
Sector Erase Time	0.5	5	sec	Excludes 00h programming prior to erasure[70]
Chip Erase Time	71		sec	
Byte Program Time	6	80	µs	Excludes system level overhead[71]
Word Program Time	6	80	µs	
Accelerated Byte/Word Program Time	4	70	µs	

Notes
68. Typical program and erase times assume the following conditions: 25°C, 3.0V V_{CC}, 100,000 cycles; checkerboard data pattern.
69. Under worst case conditions of 90°C, V_{CC} = 2.7V, 1,000,000 cycles.
70. In the pre-programming step of the Embedded Erase algorithm, all bytes are programmed to 00h before erasure.
71. System-level overhead is the time required to execute the two- or four-bus-cycle sequence for the program command. See Table 12 on page 32 for further information on command definitions.
72. The device has a minimum program and erase cycle endurance of 100,000 cycles per sector.

19. Pin Capacitance

Parameter Symbol	Parameter Description	Test Setup	Max	Unit
C_{IN}	Input Capacitance (applies to A21-A0, DQ15-DQ0)	$V_{IN} = 0$	8.5	pF
C_{OUT}	Output Capacitance (applies to DQ15-DQ0, RY/BY#)	$V_{OUT} = 0$	5.5	pF
C_{IN2}	Control Pin Capacitance (applies to CE#, WE#, OE#, WP#/ACC, RESET#, BYTE#)	$V_{IN} = 0$	12	pF

Notes
73. Sampled, not 100% tested.
74. Test conditions $T_A = 25°C$, f = 1.0 MHz.

NOTES:

1. DIMENSIONS ARE IN MILLIMETERS (mm).

2. PIN 1 IDENTIFIER FOR STANDARD PIN OUT (DIE UP).

3. PIN 1 IDENTIFIER FOR REVERSE PIN OUT (DIE DOWN): INK OR LASER MARK.

4. TO BE DETERMINED AT THE SEATING PLANE -C- . THE SEATING PLANE IS DEFINED AS THE PLANE OF CONTACT THAT IS MADE WHEN THE PACKAGE LEADS ARE ALLOWED TO REST FREELY ON A FLAT HORIZONTAL SURFACE.

5. DIMENSIONS D1 AND E DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE MOLD PROTRUSION ON E IS 0.15mm PER SIDE AND ON D1 IS 0.25mm PER SIDE.

6. DIMENSION b DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION SHALL BE 0.08mm TOTAL IN EXCESS OF b DIMENSION AT MAX. MATERIAL CONDITION. DAMBAR CANNOT BE LOCATED ON LOWER RADIUS OR THE FOOT. MINIMUM SPACE BETWEEN PROTRUSION AND AN ADJACENT LEAD TO BE 0.07mm .

7. THESE DIMENSIONS APPLY TO THE FLAT SECTION OF THE LEAD BETWEEN 0.10mm AND 0.25mm FROM THE LEAD TIP.

8. LEAD COPLANARITY SHALL BE WITHIN 0.10mm AS MEASURED FROM THE SEATING PLANE.

9. DIMENSION "e" IS MEASURED AT THE CENTERLINE OF THE LEADS.

10. JEDEC SPECIFICATION NO. REF: MO-142(D)DD.
51-85183 *F

NOTES:

1. DIMENSIONING AND TOLERANCING PER ASME Y14.5M—1994 .

2. ALL DIMENSIONS ARE IN MILLIMETERS .

3. BALL POSITION DESIGNATION PER JEP95, SECTION 3, SPP–010/020.

4. ⒠ REPRESENTS THE SOLDER BALL GRID PITCH .

5. SYMBOL "MD" IS THE BALL ROW MATRIX SIZE IN THE "D" DIRECTION.
   SYMBOL "ME" IS THE BALL COLUMN MATRIX SIZE IN THE "E" DIRECTION.
   n IS THE TOTAL NUMBER OF POPULATED SOLDER BALLS FOR MATRIX SIZE MD AND ME.

6. DIMENSION "b" IS MEASURED AT THE MAXIMUM BALL DIAMETER IN A PLANE PARALLEL TO DATUM C.

7. "SD" AND "SE" ARE MEASURED WITH RESPECT TO DATUMS A AND B AND DEFINE THE
   POSITION OF THE CENTER SOLDER BALL IN THE OUTER ROW.
   WHEN THERE IS AN ODD NUMBER OF SOLDER BALLS IN THE OUTER ROW, "SD" OR "SE" = 0.
   WHEN THERE IS AN EVEN NUMBER OF SOLDER BALLS IN THE OUTER ROW, "SD" = eD/2 and "SE" = eE/2.

8. "+" INDICATES THE THEORETICAL CENTER OF DEPOPULATED BALLS.

9. A1 CORNER TO BE IDENTIFIED BY CHAMFER, LASER OR INK MARK, METALLIZED
   MARK INDENTATION OR OTHER MEANS.

21. Revision History

Document History Page

Document Title: S29JL064J, 64-Mb (8M × 8-Bit/4M × 16-Bit), 3 V, Simultaneous Read/Write Flash Document Number: 002-00856			
Rev.	**ECN No.**	**Submission Date**	**Description of Change**
**	–	06/21/2010	Initial release
*A	–	09/01/2010	**Global** Updated the data sheet designation from *Advanced Information* to *Preliminary.* Corrected spelling, capitalization, and grammatical errors. **Simultaneous Read/Write Operations with Zero Latency** Added clarification that JL064J is only offered as a dual boot device with both top and bottom boot sectors. **Ordering Information** Clarified that Note 1 applies to the Packing Type column. **Device Bus Operations** The note for the Addresses column should be Note 1, not Note 2. **RESET#: Hardware Reset Pin** Changed "Refer to AC Characteristics on page 46" to "Refer to Hardware Reset (RESET#) on page 47". **Secured Silicon Region** Clarified the Secured Silicon Indicator Bit data based on factory and customer lock status. Removed forward looking statements regarding factory locking features as they are supported in this device. **Common Flash Memory Interface (CFI)** Clarified that once in the CFI query mode, the system must write the reset command to return to reading array data. **Enter Secured Silicon Region/Exit Secured Silicon Region Command Sequence** Removed the incorrect generalizing statement that the Secured Silicon Region always contains an ESN. **Erase Suspend/Erase Resume Commands** Added clarification that "It is not recommended to program the Secured Silicon Region after an erase suspend, as proper device functionality cannot be guaranteed." In Table 10.1, corrected the Secured Silicon Region Factory Protect fourth cycle data from 81/01 to 81/41/01. **Erase and Programming Performance** Added Note 5 regarding minimum program and erase cycle endurance. **Pin Capacitance** Changed section title from "TSOP Pin Capacitance" to "Pin Capacitance". Updated values to reflect maximum capacitances for both TSOP and BGA. Removed typical capacitance values. Added specific pin clarifications to parameter descriptions. **Physical Dimensions** Updated the VBK048 package outline drawing.

Document Title: S29JL064J, 64-Mb (8M × 8-Bit/4M × 16-Bit), 3 V, Simultaneous Read/Write Flash **Document Number: 002-00856**			
Rev.	**ECN No.**	**Submission Date**	**Description of Change**
*B	–	04/07/2011	**Global** Updated the data sheet designation from Preliminary to Full Production (no designation on document). **RESET#: Hardware Reset Pin** Added warning that keeping CE# at VIL from power up through the first reset could cause erroneuous data on the first read. **Reset Command** Clarified that during an embedded program or erase, if DQ5 goes high then RY/BY# will remain low until a reset is issued **Absolute Maximum Ratings** Corrected the maximum value of WP#/ACC voltage with respect to ground from +10.5V to +9.5V **DC Characteristics** Corrected voltage for autoselect and temporary sector unprotect (VID) minimum value from 11.5V to 8.5V **Test Conditions** Changed the format of the input pulse levels and input and output timing measurement reference levels to match the JL032J data sheet format **Hardware Reset (RESET#)** Added note to "Reset Timings" figure clarifying that CE# should only go low after RESET# has gone high.
*C	–	08/24/2011	**RESET#: Hardware Reset Pin** Removed warning that keeping CE# at VIL from power up through the first reset could cause erroneuous data on the first read. **Sector Erase Command Sequence** Added clarification regarding additional sector erase commands during time-out period. **Command Definitions Table** Added Note 17 to clarify additional sector erase commands during time-out period. **Hardware Reset (RESET#)** Removed note to the "Reset Timings" figure clarifying that CE# should only go low after RESET# has gone high. **Erase and Programming Performance** Updated Byte Program Time and Word Program Time to 80 µs. **Physical Dimensions** Package drawings updated to latest version
*D	–	12/16/2011	**Global** Corrected all references in the text to the sector erase time-out period from 80 µs to 50 µs.
*E	5038713	12/08/2015	Updated to Cypress template.
*F	5705425	04/21/2017	Updated Cypress Logo and Copyright.
*G	5766160	06/07/2017	Updated Ordering Information on page 8: Added "Valid Combinations — Automotive Grade / AEC-Q100". Updated Operating Ranges on page 40: Added Automotive Temperature Range related information.
*H	6213951	08/23/2018	Updated Ordering Information on page 8: Updated Valid Combinations — Automotive Grade / AEC-Q100: Added "70 ns" speed bin related information. Updated Physical Dimensions on page 58: Updated TS 048—48-Pin Standard TSOP on page 58: Removed spec "3664 \ f16-038.10 \ 11.6.7". Added spec 51-85183 *F. Updated VBK048—48-Pin FBGA on page 59: Removed spec "g1001.2 \ f16-038.25 \ 07.13.10". Added spec 002-19063 **. Updated to new template.
