

---

## Features

- Carrier Frequency  $f_{osc}$  100 kHz to 150 kHz
- Typical Data Rate up to 5 Kbaud at 125 kHz
- Suitable for Manchester and Bi-phase Modulation
- Power Supply from the Car Battery or from 5V Regulated Voltage
- Optimized for Car Immobilizer Applications
- Tuning Capability
- Microcontroller-compatible Interface
- Low Power Consumption in Standby Mode
- Power-supply Output for Microcontroller

## Applications

- Car Immobilizers
- Animal Identification
- Access Control
- Process Control

## 1. Description

The U2270B is an IC for IDIC<sup>®</sup> read/write base stations in contactless identification and immobilizer systems.

The IC incorporates the energy-transfer circuit to supply the transponder. It consists of an on-chip power supply, an oscillator, and a coil driver optimized for automotive-specific distances. It also includes all signal-processing circuits which are necessary to transform the small input signal into a microcontroller-compatible signal.

## 2. Pin Configuration

Figure 2-1. Pinning

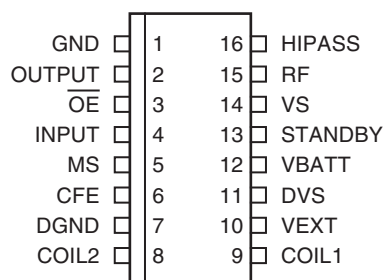

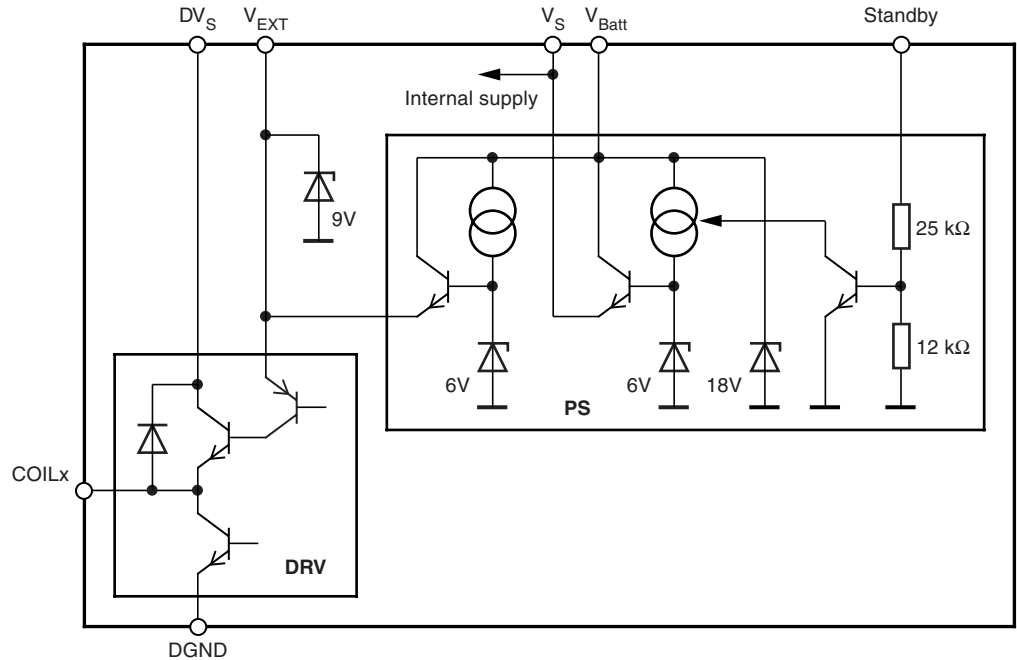

Table 2-1. Pin Description

Pin	Symbol	Function
1	GND	Ground
2	OUTPUT	Data output
3	OE	Data output enable
4	INPUT	Data input
5	MS	Mode select coil 1: common mode/differential mode
6	CFE	Carrier frequency enable
7	DGND	Driver ground
8	COIL2	Coil driver 2
9	COIL1	Coil driver 1
10	VEXT	External power supply
11	DVS	Driver supply voltage
12	VBatt	Battery voltage
13	STANDBY	Standby input
14	VS	Internal power supply (5V)
15	RF	Frequency adjustment
16	HIPASS	DC decoupling

### 3. Functional Description

#### 3.1 Power Supply (PS)

**Figure 3-1.** Equivalent Circuit of Power Supply and Antenna Driver

The U2270B can be operated with one external supply voltage or with two externally-stabilized supply voltages for an extended driver output voltage or from the 12V battery voltage of a vehicle. The 12V supply capability is achieved via the on-chip power supply (see Figure 3-1). The power supply provides two different output voltages,  $V_S$  and  $V_{EXT}$ .

$V_S$  is the internal power supply voltage for everything except for the driver circuit. Pin  $V_S$  is used to connect a block capacitor.  $V_S$  can be switched off by the  $STANDBY$  pin. In standby mode, the chip's power consumption is very low.  $V_{EXT}$  is the supply voltage of the antenna's pre-driver. This voltage can also be used to operate external circuits, such as a microcontroller. In conjunction with an external NPN transistor, it also establishes the supply voltage of the antenna coil driver,  $DV_S$ .

## 3.2 Operation Modes to Power the U2270B

The following section explains the three different operation modes to power the U2270B.

### 3.2.1 One-rail Operation

All internal circuits are operated from one 5V power rail (see [Figure 3-2](#)). In this case,  $V_S$ ,  $V_{EXT}$  and  $D_{VS}$  serve as inputs.  $V_{Batt}$  is not used but should also be connected to that supply rail.

**Figure 3-2.** One-rail Operation Supply

### 3.2.2 Two-rail Operation

In this application, the driver voltage,  $D_{VS}$ , and the pre-driver supply,  $V_{EXT}$ , are operated at a higher voltage than the rest of the circuitry to obtain a higher driver-output swing and thus a higher magnetic field (see [Figure 3-3](#)).  $V_S$  is connected to a 5V supply, whereas the driver voltages can be as high as 8V. This operation mode is intended to be used in situations where an extended communication distance is required.

**Figure 3-3.** Two-rail Operation Supply

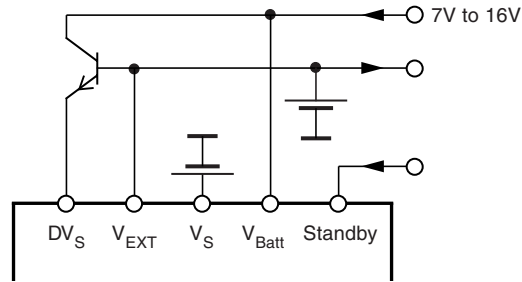

### 3.2.3 Battery-voltage Operation

Using this operation mode,  $V_S$  and  $V_{EXT}$  are generated by the internal power supply (see [Figure 3-4 on page 6](#)). For this mode, an external voltage regulator is not needed. The IC can be switched off via the STANDBY pin.  $V_{EXT}$  supplies the base of an external NPN transistor and external circuits, like a microcontroller (even in standby mode).

Pin  $V_{EXT}$  and  $V_{Batt}$  are overvoltage protected via internal Zener diodes (see [Figure 3-1 on page 4](#)). The maximum current into the pins is determined by the maximum power dissipation and the maximum junction temperature of the IC.

**Figure 3-4.** Battery Operation

**Table 3-1.** Characteristics of the Various Operation Modes

Operation Mode	External Components Required	Supply-voltage Range	Driver Output Voltage Swing	Standby Mode Available
One-rail operation	1 voltage regulator 1 capacitor	5V ±10%	≈ 4V	No
Two-rail operation	2 voltage regulators 2 capacitors	5V ±10% 7V to 8V	6V to 7V	No
Battery-voltage operation	1 transistor 2 capacitors Optional, for load dump protection: 1 resistor 1 capacitor	6V to 16V	≈ 4V	Yes

### 3.3 Oscillator (Osc)

The frequency of the on-chip oscillator is controlled by a current fed into the  $R_F$  input. An integrated compensation circuit ensures a wide temperature range and a supply-voltage-independent frequency which is selected by a fixed resistor between  $R_F$  (pin 15) and  $V_S$  (pin 14). For 125 kHz, a resistor value of 110 kΩ is defined. For other frequencies, use the following formula:

$$R_f[\text{k}\Omega] = \frac{14375}{f_0[\text{kHz}]} - 5$$

This input can be used to adjust the frequency close to the resonance of the antenna. For more details see Section “Applications” on page 10.

**Figure 3-5.** Equivalent Circuit of Pin  $R_F$

### 3.4 Low-pass Filter (LPF)

The fully integrated low-pass filter (4th-order Butterworth) removes the remaining carrier signal and high-frequency disturbances after demodulation. The upper cut-off frequency of the LPF depends on the selected oscillator frequency. The typical value is  $f_{Osc} / 18$ , and data rates up to  $f_{Osc} / 25$  are possible if bi-phase or Manchester encoding is used.

A high-pass characteristic results from the capacitive coupling at the input pin 4 as shown in [Figure 3-6](#). The input voltage swing is limited to  $2 V_{pp}$ . For frequency response calculation, the impedances of the signal source and LPF input (typical 210 kΩ) have to be considered. The recommended values of the input capacitor for selected data rates are given in [Section 4.](#), “Applications”, on [page 10](#).

Note: After switching on the carrier, the DC voltage of the coupling capacitor changes rapidly. When the antenna voltage is stable, the LPF needs approximately 2 ms to recover full sensitivity.

**Figure 3-6.** Equivalent Circuit of Pin Input

### 3.5 Amplifier (AMP)

The differential amplifier has a fixed gain, typically 30. The HIPASS pin is used for DC decoupling. The lower cut-off frequency of the decoupling circuit can be calculated as follows:

$$f_{cut} = \frac{1}{2 \times \pi \times C_{HP} \times R_i}$$

The value of the internal resistor  $R_i$  can be assumed to be 2.5 kΩ.

Recommended values of  $C_{HP}$  for selected data rates can be found in [Section 4.](#), “Applications”, on [page 10](#).

**Figure 3-7.** Equivalent Circuit of Pin HIPASS

### 3.6 Schmitt Trigger

The signal is processed by a Schmitt trigger to suppress possible noise and to make the signal microcontroller-compatible. The hysteresis level is 100 mV symmetrically to the DC operation point. The open-collector output is enabled by a low level at OE (pin 3).

**Figure 3-8.** Equivalent Circuit of Pin OE

### 3.7 Driver (DRV)

The driver supplies the antenna coil with the appropriate energy. The circuit consists of two independent output stages. These output stages can be operated in two different modes. In common mode, the outputs of the stages are in phase; in this mode, the outputs can be interconnected to achieve a high-current output capability. Using the differential mode, the output voltages are in anti-phase; thus, the antenna coil is driven with a higher voltage. For a specific magnetic field, the antenna coil impedance is higher for the differential mode. As a higher coil impedance results in better system sensitivity, the differential mode should be preferred.

The CFE input is intended to be used for writing data into a read/write or a crypto transponder. This is achieved by interrupting the RF field with short gaps. The various functions are controlled by the inputs MS and CFE (see "Function Table" on page 10). The equivalent circuit of the driver is shown in Figure 3-1 on page 4.

**Figure 3-9.** Equivalent Circuit of Pin MS

**Figure 3-10.** Equivalent Circuit of Pin CFE

### 3.8 Function Table

CFE	MS	COIL1	COIL2
Low	Low	High	High
Low	High	Low	High
High	Low		
High	High		

OE	Output
Low	Enabled
High	Disabled

STANDBY	U2270B
Low	Standby mode
High	Active

## 4. Applications

To achieve the system performance, consider the power-supply environment and the magnetic-coupling situation.

The selection of the appropriate power-supply operation mode depends on the quality of supply voltage. If an unregulated supply voltage in the range of  $V = 7V$  to  $16V$  is available, the internal power supply of the U2270B can be used. In this case, standby mode can be used and an external low-current microcontroller can be supplied.

If a 5V supply rail is available, it can be used to power the U2270B. In this case, check that the voltage is noise-free. An external power transistor is not necessary.

The application also depends on the magnetic-coupling situation. The coupling factor mainly depends on the transmission distance and the antenna coils. The following table lists the appropriate application for a given coupling factor. The magnetic coupling factor can be determined using Atmel®'s test transponder coil.

**Table 4-1.** Magnetic Coupling

Magnetic Coupling Factor	Appropriate Application
$k > 3\%$	Free-running oscillator
$k > 1\%$	Diode feedback
$k > 0.5\%$	Diode feedback plus frequency altering
$k > 0.3\%$	Diode feedback plus fine frequency tuning

The maximum transmission distance is also influenced by the accuracy of the antenna's resonance. Therefore, the recommendations given above are proposals only. A good compromise for the resonance accuracy of the antenna is a value in the range of  $f_{res} = 125 \text{ kHz} \pm 3\%$ . Further details concerning the adequate application and the antenna design is provided in Section "Antenna Design Hints".

The application of the U2270B includes the two capacitors  $C_{IN}$  and  $C_{HP}$  whose values are linearly dependent on the transponder's data rate. The following table gives the appropriate values for the most common data rates. The values are valid for Manchester and bi-phase code.

**Table 4-2.** Recommended Capacitor Values

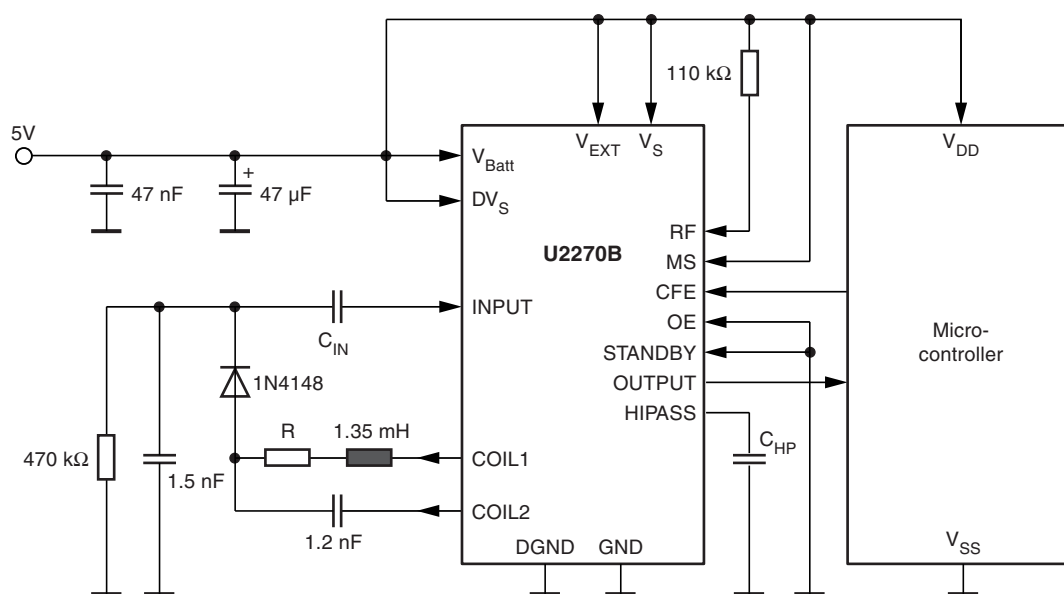

Data Rate $f = 125$ kHz	Input Capacitor ( $C_{IN}$ )	Decoupling Capacitor ( $C_{HP}$ )
$f / 32 = 3.9$ Kbits/s	680 pF	100 nF
$f / 64 = 1.95$ Kbits/s	1.2 nF	220 nF

The following applications are typical examples. The values of  $C_{IN}$  and  $C_{HP}$  correspond to the transponder's data rate only. The arrangement to fit the magnetic-coupling situation is also independent of other design issues except for one constellation. This constellation, consisting of diode feedback plus fine frequency tuning together with the two-rail power supply, should be used if the transmission distance is  $d \approx 10$  cm.

## 4.1 Application 1

Application using few external components. This application is for intense magnetic coupling only.

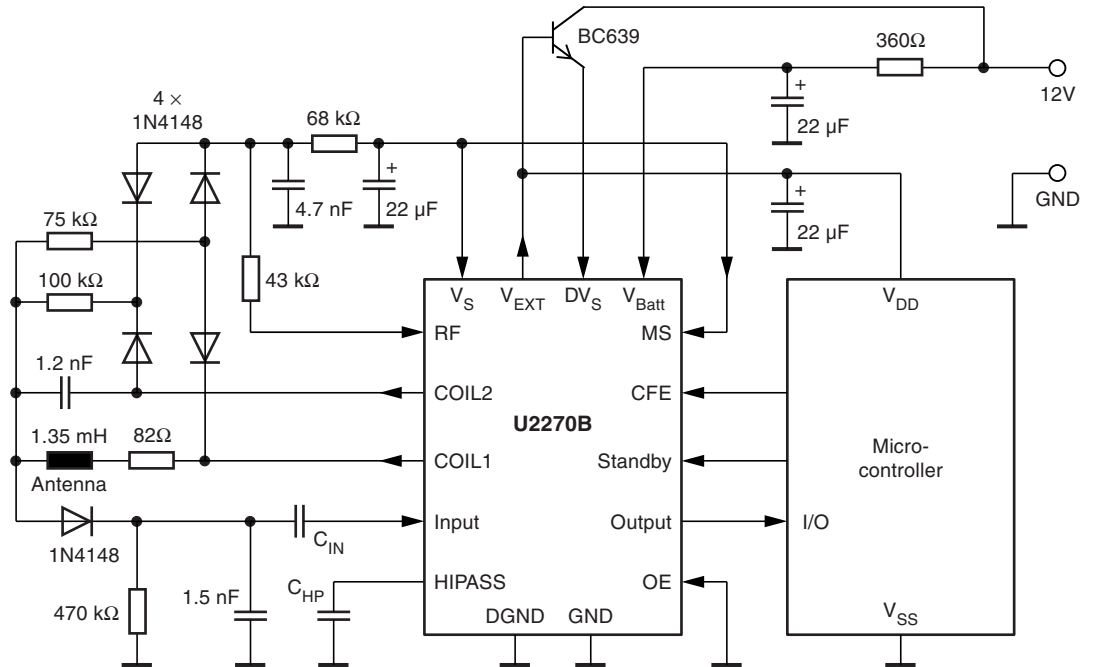

**Figure 4-1.** Application Circuit 1

## 4.2 Application 2

Basic application using diode feedback. This application allows higher communication distances than .“Application 1”

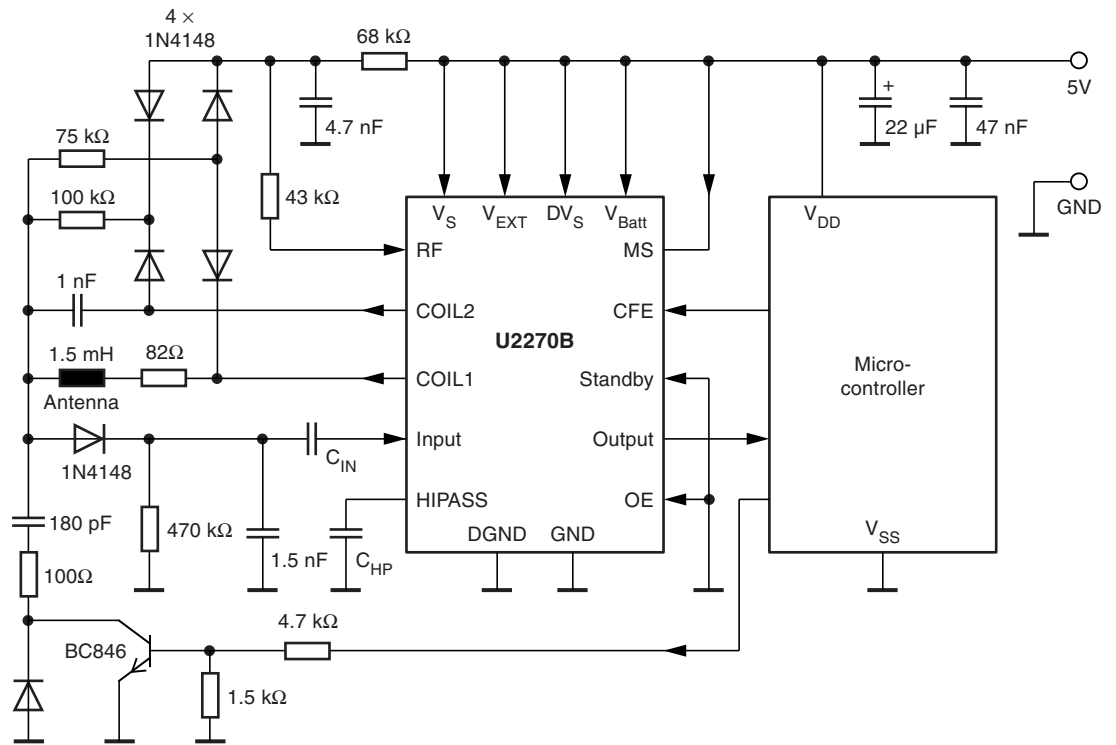

**Figure 4-2.** Application Circuit 2

4.3 Application 3

This application is comparable to “Application 2” but alters the operating frequency. This allows higher antenna resonance tolerances and/or higher communication distances. This application is preferred if the detecting microcontroller is close to the U2270B, as an additional microcontroller signal controls the adequate operating frequency.

Figure 4-3. Application Circuit 3

Note: Application examples have not been examined for series production or reliability, and no worst case scenarios have been developed. Customers who adapt any of these proposals must carry out their own testing and be convinced that no negative consequences arise from the proposals.

## 5. Absolute Maximum Ratings

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

All voltages are referred to GND (Pins 1 and 7)

Parameter	Pin	Symbol	Min.	Max.	Unit
Operating voltage	12	$V_{Batt}$	$V_S$	16	V
Operating voltage	8, 9, 10, 11, 14	$V_S, V_{EXT}, DV_S, \text{Coil 1, Coil 2}$	-0.3	8	V
Range of input and output voltages	3, 4, 5, 6, 15, 16 2 and 13	$V_{IN}$ $V_{OUT}$	-0.3 -0.3	$V_S + 0.3$ $V_{Batt}$	V
Output current	10	$I_{EXT}$		10	mA
Output current	2	$I_{OUT}$		10	mA
Driver output current	8 and 9	$I_{Coil}$		200	mA
Power dissipation SO16		$P_{tot}$		380	mW
Junction temperature		$T_j$		150	°C
Storage temperature		$T_{stg}$	-55	125	°C
Ambient temperature		$T_{amb}$	-40	105	°C

## 6. Thermal Resistance

Parameter	Symbol	Value	Unit
Thermal resistance SO16	$R_{thJA}$	120	K/W

## 7. Operating Range

All voltages are referred to GND (Pins 1 and 7)

Parameter	Pin	Symbol	Value	Unit
Operating voltage	12	$V_{Batt}$	7 to 16	V
Operating voltage	14	$V_S$	4.5 to 6.3	V
Operating voltage	10, 11	$V_{EXT}, DV_S$	4.5 to 8	V
Carrier frequency			100 to 150	kHz

## 8. Electrical Characteristics

All voltages are referred to GND (Pins 1 and 7)

Parameters	Test Conditions	Pin	Symbol	Min.	Typ.	Max.	Unit
Data output - Collector emitter - Saturation voltage	$I_{out} = 5 \text{ mA}$	2	$V_{CEsat}$			400	mV
Data output enable - Low-level input voltage - High-level input voltage		3	$V_{il}$ $V_{ih}$	2.4		0.5	V V
Data input - Clamping level low - Clamping level high - Input resistance - Input sensitivity	$f = 3 \text{ kHz}$ (square wave) Gain capacitor = 100 nF	4	$V_{il}$ $V_{ih}$ $R_{in}$ $S_{IN}$	10	2 3.8 220		V V k $\Omega$ mV <sub>pp</sub>
