3 FUNCTIONAL DESCRIPTION

3.1 DYNAMIC METERING RANGE

Accuracy is 0.1% for active energy metering over a dynamic range of 5000:1 (typical). Refer to Table-2.

Table-2 Active Energy Metering Error

Current	Power Factor	Error (%)
20mA ⩽ I < 50mA	1.0	±0.2
50mA ⩽ I ⩽ 100A		±0.1
50mA ⩽ I < 100mA	0.5 (Inductive) 0.8 (Capacitive)	±0.2
100mA ⩽ I ⩽ 100A		±0.1
Note: Shunt resistor is 250 μΩ or CT ratio is 1000:1 and load resistor is 6Ω.		

3.2 STARTUP AND NO-LOAD POWER

Startup and no-load power thresholds are programmable. The related registers are listed in Table-3.

Table-3 Threshold Configuration for Startup and No-Load Power

Threshold	Register
Threshold for Active Startup Power	PStartTh, 27H
Threshold for Active No-load Power	PNolTh, 28H

The chip will start within 1.2 times of the theoretical startup time of the configured startup power, if startup power is less than the corresponding power of 20mA when power factor or sinϕ is 1.0.

The chip has no-load status bits, the Pnoload bit (EnStatus, 46H). The chip will not output any active pulse (CF1) in active no-load state.

3.3 ENERGY REGISTERS

The M90E25 provides energy pulse output CF1 which is proportionate to active energy. Energy is usually accumulated by adding the CF1 pulses in system applications. Alternatively, the M90E25 provides energy registers. There are forward (inductive), reverse (capacitive) and absolute energy registers. Refer to Table-4.

Table-4 Energy Registers

Energy	Register
Forward Active Energy	APenergy, 40H
Reverse Active Energy	ANenergy, 41H
Absolute Active Energy	ATenergy, 42H

Each energy register is cleared after read. The resolution of energy registers is 0.1CF, i.e. one LSB represents 0.1 energy pulse.

3.4 N LINE METERING AND ANTI-TAMPERING

3.4.1 METERING MODE AND L/N LINE CURRENT SAMPLING GAIN CONFIGURATION

The M90E25 has two current sampling circuits with N line metering and anti-tampering functions. The MMD1 and MMD0 pins are used to configure the metering mode. Refer to Table-5.

Table-5 Metering Mode

MMD1	MMD0	Metering Mode	CF1 Output
0	0	Anti-tampering Mode (larger power)	CF1 represents the larger energy line. Refer to section 3.4.2.
0	1	L Line Mode (fixed L line)	CF1 represents L line energy all the time.
1	0	L+N Mode (applicable for single-phase three-wire system)	CF1 represents the arithmetic sum of L line and N line energy
1	1	Flexible Mode (line specified by the LNSel bit (MMode, 2BH))	CF1 represents energy of the specified line.

The M90E25 has two current sampling circuits with different gain configurations. L line gain can be 1, 4, 8, 16 and 24, and N line gain can be 1, 2 and 4. The configuration is made by the MMode register (2BH). Generally L line can be sampled over shunt resistor or CT. N line can be sampled over CT for isolation consideration. Note that Rogowski coil is not supported.

3.4.2 ANTI-TAMPERING MODE

Threshold

In anti-tampering mode, the power difference threshold between L line and N line can be: 1%, 2%,... 12%, 12.5%, 6.25%, 3.125% and 1.5625%, altogether 16 choices. The configuration is made by the Pthresh[3:0] bits (MMode, 2BH) and the default value is 3.125%.

Compare Method

In anti-tampering mode, the compare method is as follows:

If current metering line is L line and

$$\frac{\text{N Line Active Power} - \text{L Line Active Power}}{\text{L Line Active Power}} * 100\% > \text{Threshold}$$

N line is switched as the metering line, otherwise L line keeps as the metering line.

If current metering line is N line and

$$\frac{\text{L Line Active Power} - \text{N Line Active Power}}{\text{N Line Active Power}} * 100\% > \text{Threshold}$$

L line is switched as the metering line, otherwise N line keeps as the metering line.

This method can achieve hysteresis around the threshold automatically. L line is employed after reset by default.

Special Treatment at Low Power

When power is low, general factors such as the quantization error or calibration difference between L line and N line might cause the power difference to be exceeded. To ensure L line and N line to start up normally, special treatment as follows is adopted:

The line with higher power is selected as the metering line when both L line and N line power are lower than 8 times of the startup power but higher than the startup power.

3.5 MEASUREMENT AND ZERO-CROSSING

3.5.1 MEASUREMENT

The M90E25 has the following measurements:

- voltage rms
- current rms (L line/N line)
- mean active power (L line/N line)
- voltage frequency
- power factor (L line/N line)
- phase angle between voltage and current (L line/N line)
- mean apparent power (L line/N line)

The above measurements are all calculated with fiducial error except for frequency. The frequency accuracy is 0.01Hz, and the other measurement accuracy is 0.5%. Fiducial error is calculated as follow:

$$\text{Fiducial\_Error} = \frac{U_{mea} - U_{real}}{U_{FV}} * 100\%$$

Where U_{mea} is the measured voltage, U_{real} is the actual voltage and U_{FV} is the fiducial value.

Table-6 The Measurement Format

Measurement	Fiducial Value (FV)	M90E25 Defined Format	Range	Comment
Voltage rms	Un	XXX.XX	0~655.35V	
Current rms[note 1, note 2]	Imax as 4Ib	XX.XXX	0~65.535A	
Active Power[note 1]	maximum power as Un*4Ib	XX.XXX	-32.768~+32.767 kW	Complement, MSB as the sign bit
Apparent Power[note 1]	Un*4Ib	XX.XXX	0~+32.767 kVA	Complement, MSB always '0'
Frequency	fn	XX.XX	45.00~65.00 Hz	
Power Factor[note 3]	1.000	X.XXX	-1.000~+1.000	Signed, MSB as the sign bit
Phase Angle[note 4]	180°	XXX.X	-180°~+180°	Signed, MSB as the sign bit

Note 1: All registers are of 16 bits. For cases when the current and active/apparent power goes beyond the above range, it is suggested to be handled by microcontroller (MCU) in application. For example, register value can be calibrated to 1/2 of the actual value during calibration, then multiply 2 in application. Note that if the actual current is twice of that of the M90E25, the actual active/apparent power is also twice of that of the chip.
Note 2: The accuracy is not guaranteed when the current is lower than 15mA. Note that the tolerance is 25 mA at I_{FV} of 5A and fiducial accuracy of 0.5%.
Note 3: Power factor is obtained by active power dividing apparent power
Note 4: Phase angle is obtained when voltage/current crosses zero at the frequency of 256kHz. Precision is not guaranteed at small current.

3.5.2 ZERO-CROSSING

The ZX pin is asserted when the sampling voltage crosses zero. Zero-crossing mode can be configured to positive zero-crossing, negative zero-crossing and all zero-crossing by the Zxcon[1:0] bits (MMode, 2BH). Refer to section 6.4.

The zero-crossing signal can facilitate operations such as relay operation and power line carrier transmission in typical smart meter applications.

3.6 CALIBRATION

Calibration includes metering and measurement calibration.

Metering Calibration

The M90E25 design methodology guarantees the accuracy over the entire dynamic range, after metering calibration at one specific current, i.e. the basic current of I_b.

The calibration procedure includes the following steps:

1. Calibrate gain at unity power factor;
2. Calibrate phase angle compensation at 0.5 inductive power factor.

Generally, line current sampling is susceptible to the circuits around the sensor when shunt resistor is employed as the current sensor in L line. For example, the transformer in the energy meter's power supply may conduct interference to the shunt resistor. Such interference will cause perceptible metering error, especially at low current conditions. The total interfere is at a statistically constant level. In this case, the M90E25 provides the power offset compensation feature to improve metering performance.

L line and N line need to be calibrated sequentially.

Measurement Calibration

Measurement calibration includes gain calibration for voltage rms and current rms.

Considering the possible nonlinearity around zero caused by external components, the M90E25 also provides offset compensation for voltage rms, current rms and mean active power.

The M90E25 design methodology guarantees automatic calibration for frequency, phase angle and power factor measurement.

3.7 RESET

The M90E25 has an on-chip power supply monitor circuit with built-in hysteresis. The M90E25 only works within the voltage range.

The M90E25 has three means of reset: power-on reset, hardware reset and software reset. All registers resume to their default value after reset.

Power-on Reset: Power-on reset is initiated during power-up. Refer to section 6.3.

Hardware Reset: Hardware Reset is initiated when the $\overline{\text{reset}}$ pin is pulled low. The width of the reset signal should be over 200μs.

Software Reset: Software Reset is initiated when '789AH' is written to the software reset register (SoftReset, 00H).

4 INTERFACE

4.1 SERIAL PERIPHERAL INTERFACE (SPI)

SPI is a full-duplex, synchronous channel. There are two SPI modes: four-wire mode and three-wire mode. In four-wire mode, four pins are used: $\overline{CS}$, SCLK, SDI and SDO. In three-wire mode, three pins are used: SCLK, SDI and SDO. Data on SDI is shifted into the chip on the rising edge of SCLK while data on SDO is shifted out of the chip on the falling edge of SCLK. The LastSPIData register (06H) stores the 16-bit data that is just read or written.

4.1.1 FOUR-WIRE MODE

In four-wire mode, the $\overline{CS}$ pin must be driven low for the entire read or write operation. The first bit on SDI defines the access type and the lower 7-bit is decoded as address.

Read Sequence

As shown in Figure-3, a read operation is initiated by a high on SDI followed by a 7-bit register address. A 16-bit data in this register is then shifted out of the chip on SDO. A complete read operation contains 24 cycles.

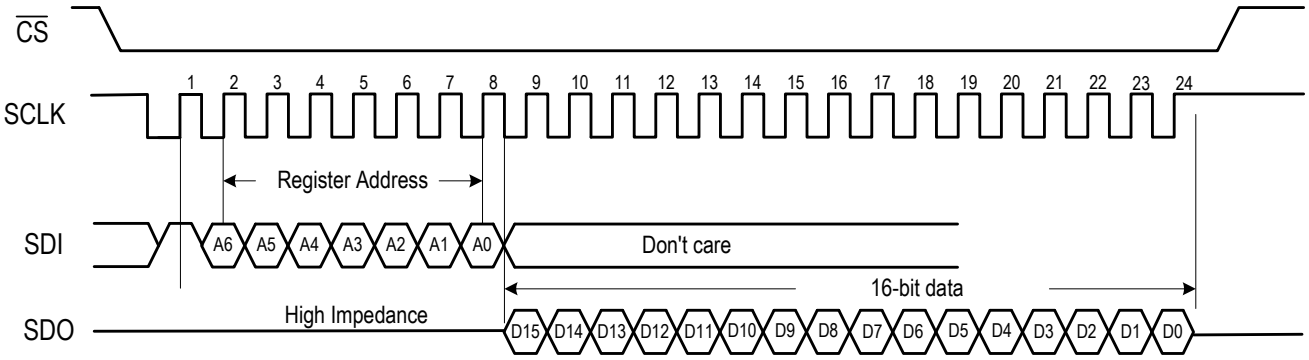

Figure-3 Read Sequence in Four-Wire Mode

Write Sequence

As shown in Figure-4, a write operation is initiated by a low on SDI followed by a 7-bit register address. A 16-bit data is then shifted into the chip on SDI. A complete write operation contains 24 cycles.

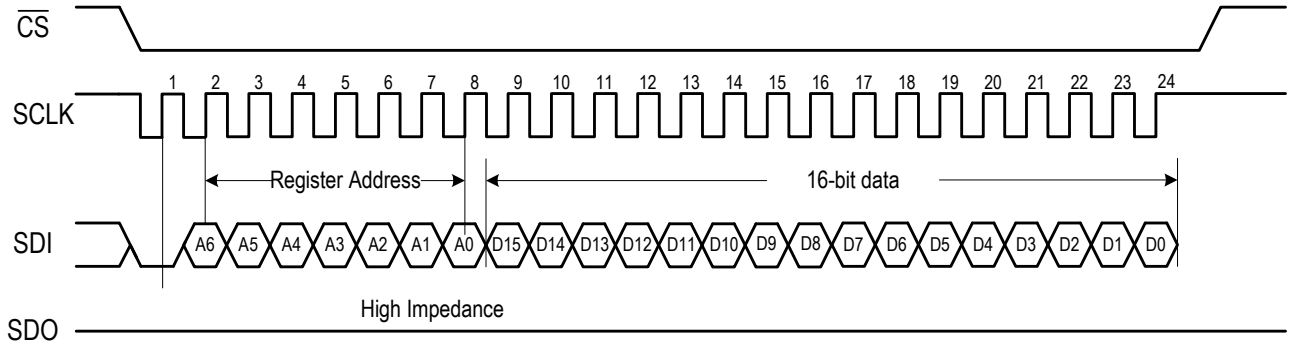

Figure-4 Write Sequence in Four-Wire Mode

4.1.2 THREE-WIRE MODE

In three-wire mode, $\overline{CS}$ is always at low level. When there is no operation, SCLK keeps at high level. The start of a read or write operation is triggered if SCLK is consistently low for at least 400μs. The subsequent read or write operation is similar to that in four-wire mode. Refer to Figure-5 and Figure-6.

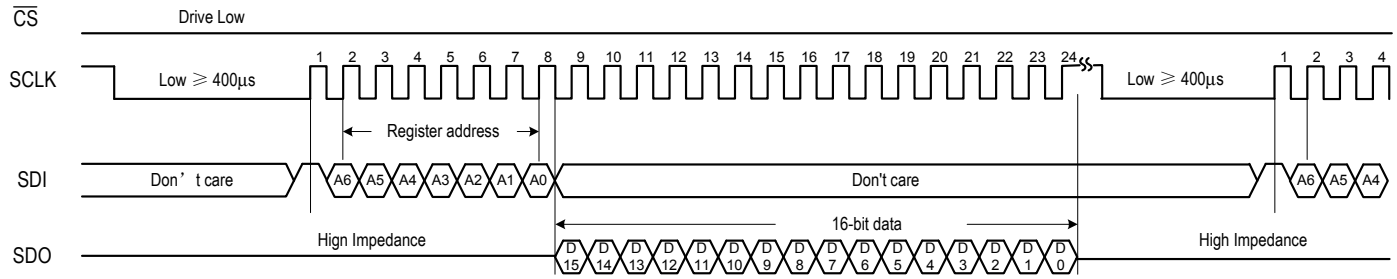

Figure-5 Read Sequence in Three-Wire Mode

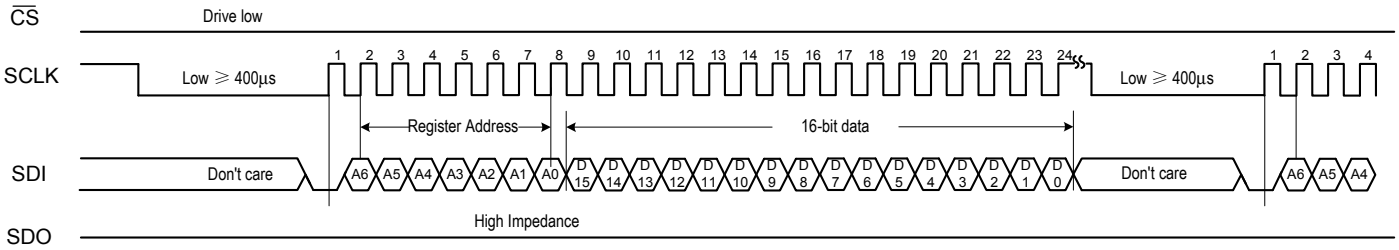

Figure-6 Write Sequence in Three-Wire Mode

4.1.3 TIMEOUT AND PROTECTION

Timeout occurs if SCLK does not toggle for 6ms in both four-wire and three-wire modes. When timeout, the read or write operation is aborted.

If there are more than 24 SCLK cycles when $\overline{CS}$ is driven low in four-wire mode or between two starts in three-wire mode, writing operation is prohibited while normal reading operation can be completed by taking the first 24 SCLK cycles as the valid ones. However, the reading result might not be the intended one.

A read access to an invalid address returns all zero. A write access to an invalid address is discarded.

Table-7 and Table-8 list the read or write result in different conditions.

Table-7 Read / Write Result in Four-Wire Mode

Condition			Result	
Operation	Timeout	SCLK Cycles[note 1]	Read/Write Status	LastSPIData Register Update
Read	-[note 2]	>=24	Normal Read	Yes
	-[note 2]	<24	Partial Read	No
Write	No	=24	Normal Write	Yes
	No	!=24	No Write	No
	Yes	-	No Write	No

Note 1: The number of SCLK cycles when $\overline{CS}$ is driven low or the number of SCLK cycles before timeout if any.
Note 2: '-' stands for Don't Care.

Table-8 Read / Write Result in Three-Wire Mode

Condition			Result	
Operation	Timeout	SCLK Cycles[note 1]	Read/Write Status	LastSPIData Register Update
Read	No	>=24[note 2]	Normal Read	Yes
	Timeout after 24 cycles	>24	Normal Read	Yes
	Timeout before 24 cycles	-[note 3]	Partial Read	No
	Timeout at 24 cycles	=24	Normal Read	Yes
Write	No	=24	Normal Write	Yes
	No	!=24	No Write	No
	Yes	-	No Write	No

Note 1: The number of SCLK cycles between 2 starts or the number of SCLK cycles before timeout if any.
Note 2: There is no such case of less than 24 SCLK cycles when there is no timeout in three-wire mode, because the first few SCLK cycles in the next operation is counted into this operation. In this case, data is corrupted.
Note 3: '-' stands for Don't Care.

4.2 WARNOUT PIN FOR FATAL ERROR WARNING

Fatal error warning is raised through the WarnOut pin in two cases: checksum calibration error and voltage sag.

Calibration Error

The M90E25 performs diagnosis on a regular basis for important parameters such as calibration parameters and metering configuration. When checksum is not correct, the CalErr[1:0] bits (SysStatus, 01H) are set, and both the WarnOut pin and the IRQ pin are asserted. When checksum is not correct, the metering part does not work to prevent a large number of pulses during power-on or any abnormal situation upon incorrect parameters.

Voltage Sag

Voltage sag is detected when voltage is continuously below the voltage sag threshold for one cycle which starts from any zero-crossing point. Voltage threshold is configured by the SagTh register (03H). Refer to section 6.5.

When voltage sag occurs, the SagWarn bit (SysStatus, 01H) is set and the WarnOut pin is asserted if the FuncEn register (02H) enables voltage sag warning through the WarnOut pin. This function helps reduce power-down detection circuit in system design. In addition, the method of judging voltage sag by detecting AC side voltage eliminates the influence of large capacitor in traditional rectifier circuit, and can detect voltage sag earlier.

4.3 LOW COST IMPLEMENTATION IN ISOLATION WITH MCU

The following functions can be achieved at low cost when the M90E25 is isolated from the MCU:

SPI: MCU can perform read and write operations through low speed optocoupler (e.g. PS2501) when the M90E25 is isolated from the MCU. The SPI interface can be of 3-wire or 4-wire.

Energy Pulses CF1: Energy can be accumulated by reading values in corresponding energy registers. CF1 can also connect to the optocoupler and the energy pulse light can be turned on by CF1.

Fatal Error WarnOut: Fatal error can be acquired by reading the CalErr[1:0] bits (SysStatus, 01H).

IRQ: IRQ interrupt can be acquired by reading the SysStatus register (01H).

Reset: The M90E25 is reset when ‘789AH’ is written to the software reset register (SoftReset, 00H).

It is suggested to set PL_constant as a multiple of 4 so as to double or redouble Meter Constant in low current state to save verification time. Note: PLconstH takes effect after PLconstL are configured. For details, please refer to application note 46101.

CS1_7	CS1_6	CS1_5	CS1_4	CS1_3	CS1_2	CS1_1	CS1_0

Bit	Name	Description
15 - 0	CS1[15:0]	The CS1 register should be written after the 21H-2BH registers are written. Suppose the high byte and the low byte of the 21H-2BH registers are shown in below table.

Register Address	High Byte	Low Byte
21H	H_{21}	L_{21}
22H	H_{22}	L_{22}
23H	H_{23}	L_{23}
24H	H_{24}	L_{24}

29H	H_{29}	L_{29}
2AH	H_{2A}	L_{2A}
2BH	H_{2B}	L_{2B}

The calculation of the CS1 register is as follows:

The low byte of 2CH register is: $\mathbf{L_{2C}}$=MOD($\mathbf{H_{21}}$+$\mathbf{H_{22}}$+...+$\mathbf{H_{2B}}$+$\mathbf{L_{21}}$+$\mathbf{L_{22}}$+...+$\mathbf{L_{2B}}$, 2^8)
The high byte of 2CH register is: $\mathbf{H_{2C}}$=$\mathbf{H_{21}}$ XOR $\mathbf{H_{22}}$ XOR ... XOR $\mathbf{H_{2B}}$ XOR $\mathbf{L_{21}}$ XOR $\mathbf{L_{22}}$ XOR ... XOR $\mathbf{L_{2B}}$
A part of registers are not used. These registers can be dealed as 0000H in CS calculation.

The M90E25 calculates CS1 regularly. If the value of the CS1 register and the calculation by the M90E25 is different when CalStart=8765H, the CalErr[1:0] bits (SysStatus, 01H) are set and the WarnOut and IRQ pins are asserted.
Note: The readout value of the CS1 register is the calculation by the M90E25, which is different from what is written.

5.4 ENERGY REGISTER

Theory of Energy Registers

The internal energy resolution is 0.01 pulse. Within 0.01 pulse, forward and reverse energy are counteracted. When energy exceeds 0.01 pulse, the respective forward/reserve energy is increased. The forward and reverse energy are not counteracted in absolute energy registers. Take the example of active energy, suppose:
T0: Forward energy is 12.34 pulses and reverse energy is 1.23 pulses;
From T0 to T1: 0.005 forward pulse appeared
From T1 to T2: 0.004 reverse pulse appeared
From T2 to T3: 0.003 reverse pulse appeared

	T0	T1	T2	T3
Forward Active Pulse	12.34	12.345	12.341	12.34
Reserve Active Pulse	1.23	1.23	1.23	1.232
Absolute Active Pulse	13.57	13.575	13.579	13.582

When forward/reverse energy or absolute energy reaches 0.1 pulse, the respective register is updated. When forward/reverse energy or absolute energy reaches 1 pulse, the CF1 pins outputs pulse and the REVP/REVQ bits (EnStatus, 46H) are updated.
Absolute energy might be more than the sum of forward and reverse energies. If “consistency” is required between absolute energy and forward/reverse energy in system application, absolute energy can be obtained by calculating the readout of the forward and reverse energy registers.
